I do not believe that any of us would advocate abandoning the reporting of "causes of death." With all its faults, it does give us valuable information that we cannot well obtain elsewhere. But it is most important for us to realize the severe limitations on the information we can hope to get from universal reporting of causes. Most definitely, we cannot expect nation-wide figures to give us specialized information which should be based on highly refined studies. If the death or birth certificate includes questions which cannot be accurately answered in the absence of highly specialized knowledge, it does not follow that everyone who fills out such a certificate becomes thereby a qualified specialist. What it does mean is that the few answers made in full accord with the facts are snowed under by the great majority of replies made in the light of pure or relative ignorance. If, in addition, we try for "completeness" and insist that everyone whosoever shall make some sort of answer to the ques-

tion, we merely turn the snowstorm into a blizzard and insure the thorough blockading of all roads to knowledge.

The logical answer to this problem is to restrict special information to the results of special studies. These may be as inclusive as possible under limitations of money and of personnel, but must always primarily be as expert and as unbiased as it is possible to devise them. In settling technical problems, there is no substitute for technical investigations, for expert knowledge and skill.

The reporting of deaths from tuberculosis, if reasonably accurate, will give us some important information of a rather simple nature. It cannot answer many of the special questions which are of prime importance to the administrator as well as to the epidemiologist. Special studies made in clinical environments can settle only some aspects of the problems.

To get a full answer, the disease must be studied where and as it occurs; in the population itself. But the agency which deals with populations in the field, and with their disease problems, is precisely the health department. It is in best position to make continued studies of a group or area, to bring diagnostic aids into play, to use epidemiological and statistical methodology. This type of study can give clues to many things: What is the course of tuberculosis in the community? Who are the individuals most at risk of contracting clinical disease? Who are those to whom the limited clinical facilities can most effectively be extended? And, as a by-product, the general reporting of morbidity and

mortality from tuberculosis in the area studied gains an exactness far superior to that in other areas.

It is most encouraging to see health departments set up studies of just this sort, in various fields. Naturally, the aims include quick and accurate answers to pressing administrative problems, but may and do range much farther than immediate practicability. It is obvious that such studies demand the most expert of statistical guidance and analysis; it is no surprise to see that health agencies interested in making them have also expert and efficient departments of statistics.

It is interesting to see that two of the most significant developments in recent years in the field of vital statistics derive their usefulness partly from a realization of the stratification of reliability of information. At one end of the scale, much more complete use is made of data which are inherently the most reliable in bulk. At the other, emphasis is laid on the analysis of information which, even though limited in amount, is as accurate as it can be made.

It will be interesting, in the future, to see whether it will be possible to devise means of better utilization of the mass of statistics lying in the center zone of reliability, that part lying between the extremes of mass accuracy and of the demand for highly specialized knowledge. This zone may, for all we know, be narrowing. It is conceivable that we shall be able to improve on the accuracy of much information which is now doubtful, and that the scope of our special studies will spread more and more to fill any remaining gap.

A Discussion of Bacteriological Standards for Dehydrated Foods*

HARRY E. GORESLINE, PH.D., F.A.P.H.A.

*Food Technologist, Poultry Branch, Production and Marketing Administration,
U. S. Department of Agriculture, Washington, D. C.*

IN recent years there has been a growing interest on the part of consumers in the wholesomeness, quality, and nutritional value of the food products which they buy. The manufacture of raw products into forms ready for use makes it necessary for the consumer to rely on the integrity of the manufacturer, or on certain regulations, to be assured that the food product purchased is manufactured under such conditions as to present no public health hazard and that it is of such sanitary quality as to be eaten with confidence. In order to give such assurances it is necessary to establish some uniformity of operation and to express food qualities in a uniform manner. One way of accomplishing uniformity is to establish standards which will serve as a guide to the manufacturer and be informative to the consumer.

Standards have been established for certain foods and are proving their worth. The recent growth of the dehydrated foods industry and the appearance of new dehydrated products on the shelf make it seem desirable to determine the need of standards for these products. Several kinds of standards may be applied to a food product. Standards of identity and standards of quality apply to the physical and chemical make-up of the product and its

acceptability as an article of food. They aid the consumer in purchasing more intelligently and in getting his money's worth. Bacteriological standards are somewhat different but they apply directly to the above standards and are important from a public health standpoint. Foods might meet all standards of quality and identity, and be of excellent nutritional value, yet be contaminated with pathogenic microorganisms and thus present a public health hazard. On the other hand pathogenic microorganisms may be absent, yet due to faulty manufacturing techniques the product may be teeming with bacteria which markedly affect the quality and general acceptability of the food. In establishing any standard these two phases of the problem must be taken into consideration.

Fortunately, dried and dehydrated foods have a remarkably clean bill of health from the standpoint of food poisoning and other infections. Nichols¹ points out, "On the whole, the public health record of dried foods is remarkably clear. The almost complete absence of food poisoning or infection cases in which dried foods have been involved indicates that they are among the safest forms of food . . . While but little work has been done on the survival of pathogenic bacteria (in dried foods) the indications are that danger from this respect is remote." This does not mean that dried foods should be considered safe under all conditions, but it points

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946

to the fact that, as a rule, they can be accepted with confidence.

Such statements show that, if bacteriological standards are to be set up, the primary emphasis should be from a sanitary or operating standpoint, and secondly, from the standpoint of public health. It can be shown throughout the food industry that the growth of spoilage bacteria is detrimental to the quality of the final product. So close is the correlation between spoilage and the deterioration of quality that bacterial standards should be a part of any quality standard of dried foods, since it is often possible to explain the reason for poor condition by a bacteriological examination. Bacteriological examinations of such products not only give evidence of conditions that existed during the manufacture but also point the way toward proper control of the processes. Fitzgerald² states that, "The problem of establishing factory sanitation methods and standards is as important as the question of quality standards. If products ever become public health hazards, then standards will be imposed on the industry . . . Sanitation standards are, nevertheless, a necessary adjunct of any quality control program. The very best grading standards can be nullified by poor sanitary techniques." Clague³ points out that "The mere presence of bacteria, yeasts, or molds on dried foods does not of itself constitute a spoilage hazard. Modern packaging is such that moisture may be kept from gaining access to dried foods, thus eliminating the danger of spoilage. So the principal value of the microbiological examination of dehydrated foods would be to determine the comparative cleanliness of the process used from the time the raw product enters the factory until the finished product reaches the consumer."

It is evident that any bacterial standards must have their roots in the sanitary controls over food manufacturing processes. In order to be assured of any

uniformity of results from the microbiological standpoint there must be established as rigid a set of operating standards for plants that process foods as the standards established for the final products. This means that if bacterial standards are to be established for any food commodity there must also be established an accompanying set of suggested sanitary operating standards with which to meet these requirements. This does not necessarily mean plant supervision by an outside agency, but it does mean that some organized supervision in the plant is necessary in order to manufacture a high quality product. Good sanitary practice ought to come instinctively to a food handler, but, alas, it is found too infrequently and often only under the shadow of compulsion. Many public health control agencies find full-time employment in establishing good sanitary practices in places where it would seem natural to find them if for no other reason than the monetary return from efficiency. Sanborn⁴ calls attention to the fact that " . . . First, food products prepared under unsanitary conditions are almost certain to contain filth, sometimes gross enough to affect flavor or appearance to the unaided eye, and always manifest to the microscopist. This may consist of mold or other microorganisms, insects or insect parts, rodent hairs or excreta—any or all of them," and further. "Bacteriology teaches that the heavier the initial infection, the more severe is the process requirement for sterilization. Infection at some insanitary point in the preparation line, therefore, may result in serious commercial spoilage or loss of quality due to more vigorous processing to overcome the heavier bacterial infestation." Many people have to learn the hard way that it costs money to be slipshod and unsanitary in food preparation.

Let us look at dried fruits, vegetables, eggs, and meat for a clearer picture of

the need for bacterial standards for such products. Some of the drying methods were developed before many of the principles of sanitation were established, and it is difficult to change them. Other methods have been developed with good sanitary practices in mind.

DRIED FRUITS

Dried fruits are contaminated with microorganisms when they leave the orchard, but they pick up additional infections as they are processed. Fortunately, as Nichols¹ points out, the high acid and low protein content of fruits make them unfavorable media for the growth of pathogenic bacteria. The infections are largely from yeasts and acid-tolerant spoilage bacteria. Phaff, et al.⁵ describe the handling of prunes in drying and state that the water used in washing the prunes is recirculated over a long period of time and becomes heavily contaminated with microorganisms. This water may so heavily infect the prunes that washing with fresh water is insufficient to satisfactorily reduce the bacterial population. Other methods of operation may tend to further contaminate them. Even so, the use of germicides and dehydration yields a product with few live yeasts and molds. Mrak⁶ discusses this phase of the drying problem and indicates that recontamination in handling after drying may result in considerable loss and undesirable changes in the fruit in storage. In some dried fruits gas fumigation may be used to control microorganisms. Whelton, et al.⁷ elaborate on this phase.

The sun-drying of fruits has the disadvantage of bacterial contamination while fruit is exposed in the open without the killing effects of heat as found in mechanical dehydration. Moreover, certain fruits deteriorate when they are heated and sun-drying must be used. Except for accidental contamination by pathogens, dried fruits would seem to offer no public health hazard. Bacterial

standards should be concerned largely with control of handling and storage.

DRIED VEGETABLES

Vegetables are non-acid and, therefore, are subject to the growth of most types of microorganisms. Hucker, et al.⁸ report a study of food processing plants from the microbiological standpoint. They found that although blanching and other operations reduce the numbers of microorganisms, recontamination in processing may occur. They found that the dried food from nine of twelve vegetable dehydrating plants was contaminated with members of the coliform group, and that "in 80 per cent of the cases, presumptive tests could be secured for coliform organisms on the finished dehydrated vegetable just prior to final packing." Jones⁹ shows that *Escherichia coli* organisms are killed during proper blanching of vegetables. This points to the fact that if *E. coli* is found in the finished product it is indicative of contamination during the final processing and handling. A definite need for bacterial standards in such products is indicated, since the presence of organisms of the coliform group have long been used as an index of cleanliness. Their presence in dehydrated vegetables would indicate unsanitary or poor operating conditions. Kitner and DeLay¹⁰ tabulate the improvement in bacterial quality obtained in a vegetable dehydrating plant through changes in the sanitary practices and in general plant conditions. He shows that sanitary conditions in operation during manufacture are definitely reflected in the final product.

Jones⁹ points out that enormous quantities of air are used in dehydrating vegetables and that the amount of contamination encountered depends largely upon the location of the plant and the types of bacteria found in the air. Good sanitary practice would require the filtration of the air.

Jones further calls attention to the fact that high bacterial counts "not only lead to earlier spoilage upon rehydration of the products but they also suggest poor sanitary conditions and methods in the plant, and may lead to the rejection of the products by health authorities."

The overloading of dryer trays as reported by Vaughan and Kuneman¹¹ shows how bacteria may grow in the food during the actual dehydrating process, even to the point of souring before becoming dry. Light tray loading prevents this.

Kitner and DeLay,¹⁰ Jones,⁹ and Haines, et al.¹² point out that the viable bacterial counts of dehydrated vegetables decrease in storage. This shows that it is difficult to use the live count except as a control in actual plant operation. The direct microscopic examination of dehydrated products seems to be the only method which will reflect the general condition of handling and drying, and serve in establishing bacterial standards.

DRIED EGGS

The expansion of the dried egg industry has added these food products to many food commodities. More research work has been done on the bacteriology of these products than any other of the dried foods under discussion here. Liquid eggs constitute a splendid medium for the growth of bacteria. The sanitary quality of dried eggs is linked largely with the manner of handling the shell eggs and the liquid before it is dried. High bacteria counts in these products indicate poor operation or handling techniques. Not only is a product with an abnormally high bacterial count likely to be of poor edible quality but Stuart, et al.¹³ have shown that egg powder of low sanitary quality does not hold up in storage.

The plate or viable bacterial count is not a true index of the bacterial quality

of an egg powder. Johns and Bernard¹⁴ point out that the survival of bacteria in egg powder is affected by such factors as type of drier, drying temperatures, rate of cooling, and length of storage. Stuart, et al.¹⁵ demonstrated that the death rate of bacteria in normal egg powder in storage was influenced by the initial moisture content. The lower the initial moisture the more rapid the death rate. Stuart, et al.¹⁶ show further that in powder of high sanitary quality the rate of bacterial death proceeds at a uniform logarithmic rate, while there is a secondary accelerated death rate in powders of low sanitary quality. These facts, therefore, make it evident that the viable bacterial count can be of little value in establishing bacterial standards unless a complete history of the sample can be furnished.

However, the direct microscopic bacterial count, which shows the dead as well as the living bacteria in the powder, is not markedly affected by such factors. Thus, a microscopic examination will indicate through the type and numbers of bacteria the general conditions of the plant during the manufacturing period. Bartram¹⁷ found that in experimentally prepared dried eggs the viable count was of limited value as an index of quality. Lepper, Bartram, and Hillig¹⁸ show that the direct microscopic examination together with the chemical determination of the products of bacterial fermentation, acetic, formic, and lactic acids, serve to indicate the quality of the final product.

So far as is known, no authenticated cases of food poisoning or other infections have been traced to dried eggs. But the fact that several types of *Salmonella* have been isolated from dried eggs makes it necessary to keep the public health aspect in view when dealing with possible bacterial standards. The presence of *Salmonella* in dried eggs, and the fact that *Salmonella* poisoning outbreaks have not been reported pre-

sents an interesting public health problem. Soloway, et al.¹⁹ have shown that *Salmonella* may be isolated from shell eggs, from the shell especially when dirty, from the egg liquid in an egg breaking room, and in egg powder. Soloway, et al.²⁰ report the isolation of *Salmonella* from 35 per cent of 5,198 samples of dried whole egg examined, and 52 *Salmonella* types were serologically identified from the isolations. Other workers, Gibbons, et al.^{21, 22} and Schneider,²³ report isolations in varying amounts.

Although the types reported as occurring in egg powder with the greatest frequency are among those found in human and animal infections, outbreaks of *Salmonella* from eating dried egg products have not been reported. It is the opinion of the author that while the *Salmonella* types isolated are serologically identical with those found in food poisoning outbreaks, their pathogenicity may have been lost by some mechanism of passage through the hen as a host or through the selective action of the lysozyme, the natural germicide in the egg. The fact that outbreaks have not occurred should not preclude the presence of such bacteria. The contamination of egg powder with *Salmonella* from a human or rodent source might prove as infectious as it would in other foods.

It is evident that bacterial standards for dried egg products would serve to assure sanitary plant operations since poor operations would be reflected in high bacterial counts, and would serve to bring about constant checks for types of bacteria known to have public health significance.

DRIED MEAT

Dehydrated meat is one of the recent developments in the dried food field. As Ritchell, et al.²⁴ pointed out, comparatively little work has been done on the microbiology of this product as com-

pared with that done on the bacteriology of uncooked or cured meats. They demonstrated that dried meats of high viable bacterial count showed a rapid decrease in storage. With initial bacterial counts of approximately 21,000,000 per gm. only 510,000 remained alive at the end of 3 weeks, 3,000 at the end of 18 weeks, and 180 after 49 weeks. Experimental work carried out by Haines and Elliot¹² demonstrated that in order to prevent bacterial growth the meat should reach 52° C. (125° F.) within the first hour of dehydration and remain above that temperature until a fairly low moisture content is reached.

In the report of the work done in the U. S. Department of Agriculture on Meat Dehydration²⁵ a resumé of the "Control of Bacteria and Molds" in dried meat manufacture may be found. As stated in this report a large number of organisms were killed in pre-cooking of the raw material at 165° F. for 30 minutes. Bacterial spores were the predominating forms found in the dehydrated product. "On the basis of the experimental work, dehydrated meat was safe, from a bacteriological point of view, when produced in accordance with federal specifications for the products . . . dehydrated meats stored under conditions unfavorable for mold growth, as previously indicated, should offer no opportunity for contamination or growth of food poisoning bacteria. Reconstituted meat should be consumed promptly, since tests showed it is to be an excellent bacterial medium."

Dried meat with high bacterial counts would not only indicate poor sanitary conditions of manufacture, but also that the product would spoil quickly upon reconstitution. For purposes of plant control, indication of sanitary quality, and as a guide in use, the establishment of bacterial standards would be indicated. Here again it would be necessary to resort to direct microscopic methods

to develop the true picture of the conditions of manufacture.

The Committee on Foods (except milk) of the American Public Health Association²⁶ opened the question of establishing bacterial standards for dehydrated foods and pointed out that it would be necessary to determine what methods and standards could be applied to all classes of dehydrated foods. Jones⁹ discussed, at some length the establishment of bacterial standards for dehydrated vegetables. He states, "The setting up of standards based upon the microbial content of dehydrated products presents considerable difficulty. It has previously been pointed out that a low bacteria count may be the result of storage at relatively high temperatures, e.g., room temperature . . . From the results presented in this paper it is apparent that a total count of not more than 100,000 bacteria per gram of blanched product may be readily achieved. Coliform bacteria should be absent in 1/200 gram product." He goes on to say that if coliforms are found in 1/20 gm., steps should be taken to check the processing. Haines and Elliot¹¹ suggested that a bacterial "production standard" might be set up for use in manufacture, and a "consumption standard" be used for utilization purposes. This would prove of value from a manufacturing standpoint but would not be practicable for checking samples of material offered for sale unless a complete history were at hand.

There is not enough information available upon which to base the limits of bacterial standards for all products. Additional research is needed and it should be directed toward determining the basis for reasonable standards. Since such standards would be used largely to determine the sanitary conditions of manufacture they should be determined by surveys of actual operation. It would seem that they should be a part of the standards of quality. No product should

be manufactured under conditions that would be revolting or detrimental to the consumer, and consumers of dehydrated foods are entitled to an assurance of the proper method of preparing the products. Jones⁹ makes an excellent point that, "Plant sanitation deserves greater emphasis. Workers should have impressed upon them the fact that they are handling a food product and that personal hygiene and cleanliness are essential."

Although there is very little to indicate the presence of pathogenic microorganisms, which have retained their pathogenicity, in dehydrated foods, any bacterial standards should provide that the food is free of those organisms known to be pathogenic to man. This should also take into consideration those bacterial types generally used as indices of contamination, such as *E. coli*.

Reports in the literature and experience of actual operations indicate the need for bacterial standards for dried and dehydrated foods. Such standards should be on a reasonable basis and should take into consideration any variations which might be found to exist in normal operations with a good product. All such standards should be for voluntary application or for adoption as a code by the industry.

Perhaps the most useful standard would be that for bacterial count by the direct microscopic method. Certain modifications would be necessary before the method could be used for all products. Reasonable limits could be set, based upon conditions of reasonable plant operation, and these would reflect the sanitary quality of the dehydrated product just as other tests reflect the edible quality. It would then be necessary to establish standard methods of operation under which the bacterial standards could be met; otherwise, no uniformity of results could be expected. The lead in establishing and coördinating such standards should be taken by

such an organization as the Food and Nutrition Section of the American Public Health Association.

The Problem of Reconstituted Milk*

GEORGE H. HAUSER, M.D., AND WILLIAM H. KING

Director, Division of Laboratories, Louisiana State Department of Health and City of New Orleans; and Chief, Food and Drug Section, Louisiana State Department of Health, New Orleans, La.

RECONSTITUTED milk, the production and use of which have greatly increased in many parts of the world in recent years, is not of recent origin. Over seven centuries ago¹ the world's most famous traveler Marco Polo while visiting the Mongol Emperor Kublai Khan, realized the value of dried and reconstituted milk. These Mongols were nomads who required convenient food for their many expeditions. Quoting Polo, "they have milk dried into a kind of paste to carry with them. When they go on a journey, every man takes some 10 lbs. of this dried milk with him, and of a morning he will take half a pound of it and put it into his leather bottle, with as much water as he pleases, so as he rides along, the milk paste and the water get well churned together into a kind of pap, and that makes his dinner." There is some evidence that the ancient Egyptians may have used dried milk, but the interesting report made by Marco Polo is the first account of such a product.

Condensed milk has been manufactured for nearly 100 years and evaporated milk for more than 60 years; however, satisfactory processes for drying milk have been developed only within the present century. Today powdered milk is used throughout the world, but this valuable commodity is of comparatively recent commercial origin.

Due to the shortage of fresh fluid milk in certain areas of this country, particularly in the South, there has been a trend toward extending local supplies of fluid milk by reconstituting milk products back to the approximate chemical composition of fluid milk with water. This was particularly true in those areas where the population was abnormally increased due to the influx of military and defense plant personnel. All indications are that the use of reconstituted milk and cream will continue.

A number of ingredients may be used for reconstituting milk; these are listed herewith: (1) skim milk powder with fresh cream, (2) skim milk powder with butter, (3) plain condensed skim milk and natural cream, (4) plain condensed milk with unsalted butter, (5) whole evaporated milk, (6) combinations of any of the above, either with water or with natural fluid milk. By far, the most common materials used for reconstituting milk in the State of Louisiana are concentrated skim milk with natural cream, with or without natural fluid milk. The State Health Department has information, however, that in some instances powdered milk may be used. Some of the milk is sold in bottles bearing caps labeled "reconstituted milk," while other reconstituted milk has been mixed with fresh fluid milk and sold in bottles labeled simply as "milk."

The Public Health "Milk Ordinance and Code,"² recommended by the

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

U. S. Public Health Service, defines reconstituted or recombined milk or cream as follows:

Reconstituted or recombined milk is a product resulting from the recombining of milk constituents with water, and which complies with the standards for milk fat and solids not fat of milk as defined herein. Reconstituted cream or recombined cream is a product resulting from the combination of dried cream, butter, or butter fat with cream, milk, skim milk, or water.

The Louisiana State Sanitary Code³ defines reconstituted or recombined milk or cream as follows:

Reconstituted or recombined milk is a product resulting from the recombining of milk constituents with fluid milk or water and which complies with the standards for milk, milk fat and solids not fat of milk as defined herein. Reconstituted or recombined cream is a product resulting from the combination of dried cream, butter, or butter fat, with cream, milk, skim milk, or water and which complies with the standards for cream as defined herein.

Both of these codes further require that all bottles, cans, packages, and other containers enclosing milk or any milk product defined in the code shall be plainly labeled with the name of the contents as given in the definition of the code. In other words, these codes recognize reconstituted milk and cream as food products which may be sold if properly labeled, and of course if they are not otherwise adulterated or misbranded.

On July 15, 1946, Act 159, enacted by the Legislature of the State of Louisiana, was signed by the Governor. This is an Act designed to protect the public health and safety, and requires all fluid cream and milk or other milk products which may be converted into fluid milk or fluid cream, shipped or transported into Louisiana, to be of the standard required by Standard Ordinance and Code of the U. S. Public Health Service and by the Sanitary Code of the Louisiana State Board of Health.

This act also provides for inspection of milk produced for shipment or transportation into this state and the conditions under which it is produced, and provides for the issuance of permits to shippers or transporters by the Louisiana State Board of Health. The Louisiana State Sanitary Code outlines the sanitary conditions under which such fluid milk must be produced. At present, regulations are being prepared governing the sanitary conditions under which milk must be produced to be used in manufacturing milk products, including the various concentrated and dried milk products.

During World War II the armed forces purchased, for use by military personnel, large quantities of concentrated milk products for shipment to areas in this country and abroad where there was a shortage of safe fluid milk. Accordingly, the Quartermaster Corps of the U. S. Army⁴ issued tentative specifications for non-fat and whole dried milk solids as well as concentrated whole and skim milk to be used in making reconstituted milk. Specifications were also issued by the Quartermaster Corps for pasteurized milk blended with reconstituted dried whole milk. The specifications included bacterial, chemical, sediment tests, and sanitary standards, not only for the products referred to above, but also for the raw milk used in their manufacture.

The American Dry Milk Institute, Inc. *Bulletin No. 906*⁵ has set up sanitary and quality standards for the dried milk industry, which involve farm sanitation and quality of milk supply, equipment and plant sanitation, handling and drying methods, analysis and grading of the finished products, and packaging requirements. In addition, the Institute published *Bulletin No. 911*,⁶ setting forth the standards for various grades of dried milk products including chemical and physical properties, bacterial count, and sediment. It

states that it is generally agreed that the bacterial count of non-fat dry milk solids is not necessarily an indication of the quality of the raw milk from which the dry product is made. The process of manufacture has a direct bearing upon the extent to which bacteria are destroyed.

In July, 1946, a letter was written to the health officer of each state requesting information regarding regulations and standards, including bacteriological and chemical tests for reconstituted milk. Forty-two replies were received and classified as shown in Table 1.

As noted in Table 1, in eight states the sale of reconstituted milk is prohibited by law, but one of these allowed it to be sold only during the war emergency.

Seven states permit sale under the Standard Milk Ordinance and Code recommended by the U. S. Public Health Service. One of these states accepts it only on the basis of the quality of the raw milk, and two require that reconstituted milk meet bacteriological standards, but these standards were not defined.

In five states it is permitted in those communities which have adopted the Standard Milk Ordinance and Code.

Thirteen states have special laws or regulations pertaining to its sale and distribution. Most of these require that it meet the minimum chemical composition of fluid milk with respect to butter fat and non-fat-solids content, and must be properly labeled. One state controls it indirectly in that all fluid milk must be produced on dairy farms within the natural milk shed which has been inspected and approved by the Dairy and Food Commission. One southern state allows its sale on an emergency permit basis. This permit is issued by the state board of health on recommendation of the county health officer if the local fluid milk supply is short. It requires

pasteurization before concentrating and during recombination, and sets a maximum standard plate count of 30,000 per ml. after pasteurization. It provides sanitary, bacteriological, and chemical standards for ingredients used in the reconstitution, including the concentrated milk ingredient, fresh whole milk, water, and plants set up for the purposes of both dehydration and rehydration.

The director of the dairy and food division of the department of agriculture of one of our northern dairy states asserted that because of the high temperature dried products are subjected to, it does not seem that these products would involve a major problem with respect to health hazards. The process or act of reconstituting milk would be the main problem, including among other things, the sanitary quality of the water used. In addition to the chemical standards for dried milk products, that state requires a standard plate count not greater than 50,000 per ml. on a reconstituted basis when the milk is reconstituted with sterile water.

Seven states have no laws or regulations governing its sale and distribution, and two of these stated that none is sold within the state.

Information received from two states was unsatisfactory for classification purposes.

The increased use of reconstituted milk by military personnel prompted Randall⁷ to investigate it from bacteriological, chemical, and biological standpoints. At the time, these studies were carried on, Randall was a Major, Veterinary Corps, United States Army, stationed in Manila, Philippine Islands.

The product used was a reconstituted milk prepared from skim milk powder shipped from California and butter from Australia to which was added water obtained from an artesian well. It was pasteurized during the reconstituting process and bottled in the usual manner for pasteurized whole milk.

Randall made bacterial and Breed counts of the skim milk powder, butter, water, and the finished product at monthly intervals. He found the bacterial plate colony count of the butter and water consistently low, while that of the skim milk powder was high. The Breed count of the skim milk powder was excessively high, indicating a probable high bacterial content of the fluid skim milk used for drying. Both the bacterial plate colony and Breed counts in the finished product were well within the prescribed limitations for Grade A pasteurized milk.

Chemical examinations of two samples of milk powder which had been stored for 5 months showed a moderate darkening of color, a decreased solubility, and a faint musty odor, but no suggestion of tallowy odor. The Kreiss test for oxidation of fat was negative, and the total solid content, including fat, of the reconstituted milk met standard requirements.

In the biological experiments conducted on rats, the vitamin content of the reconstituted milk was not appreciably changed by the reconstituting process.

Randall concluded from this experimental work, that a fluid milk can be prepared from skim milk powder, sweet (unsalted) butter, and water, that will closely approximate pasteurized cow's milk.

Tice, Tisdall, and McCreary⁸ devised a method of supplying reconstituted milk for drinking purposes to the Royal Canadian Air Forces personnel in isolated stations. This consisted in the use of gas-packed whole drug milk which was thoroughly reconstituted by means of an electric mixer, strained, and aged in a refrigerator for 24 hours before serving ice cold. They reported the aging process greatly improved the taste of the milk.

Curtis and Hileman⁹ in a study of the comparison of media and incubation

temperatures for making bacterial counts of spray process dry skim milk have shown that the use of tryptone agar with incubation at 32° C. (89.6° F.) for 48 hrs. as compared with the standard method using standard agar and incubated at 37° C. (98.6° F.) resulted in a 94 per cent increased plate count. The tryptone agar showed a marked increase over that obtained by the use of standard agar 51.9 per cent at 37° C. and 87.4 per cent at 32° C. while the reduction in the incubation temperature resulted in a similar but somewhat lesser effect—standard agar 3.5 per cent—tryptone agar 27.7 per cent.

Crossley and Johnson¹⁰ reported the bacteriological aspects of the manufacture of spray dried milk and whey powders. The bacteriological count of the final powder showed great variations and was affected by many factors, such as, the initial bacterial content of the milk, types of organisms initially in the milk, pasteurization variations, and plant cleanliness. Various types of bacteria were found. Coliform organisms were usually present but almost always in small numbers, mainly of the aerogenes type. It was also found that 48.5 per cent of the coliform strains were heat resistant as compared with 2.2 per cent of the raw milk strains. Plant contamination by heat resistant strain was an important factor. While the actual spray-drying destroyed many bacteria, some non-thermoduric species survived, and it could not be relied upon to kill pathogenic bacteria; hence the need of reliable pasteurization. During storage of the dried milk there was a considerable but variable decline in the number of bacteria, with rapid disappearance of the coliform type.

Dr. Robert S. Breed,¹¹ Chairman of the Committee on Standard Methods for the Examination of Dairy Products, of the American Public Health Association, recently made the following pertinent statement:

Fresh milk properly pasteurized is naturally to be preferred to any reconstituted milk; but the use of milk is so important from the standpoint of nutrition that there is, in my judgment, every reason to extend the use of reconstituted milk, evaporated or other type of dehydrated milks in areas where milk supplies are not sufficiently abundant to be used generally. The development of the dehydrated, evaporated, and condensed milk industry in the United States has resulted in a much larger per capita use of dairy products than would otherwise have taken place, and the nutrition of our children has been greatly benefited. Such products can normally be put on the market at prices that make them available to the general mass of the people. Experience has shown that the danger of the spread of infectious disease by the use of dehydrated or canned milk products is practically nonexistent.

Recently, however, Allen and Baer¹² have reported an outbreak of septic sore throat due to reconstituted milk. The outbreak was caused by milk from a "mechanical cow." The reconstituted milk was prepared from powdered dry milk, sweet cream, unsalted butter, and water. Beta hemolytic streptococcus was the causative organism.

When both fresh whole and dry whole milk are figured to the dry basis for comparison, using data prepared in *Tables of Food Composition in Terms of Eleven Nutrients*,¹³ there is noted little chemical difference in the two products.

Nevens and Shaw¹⁴ studied, in feeding tests with albino rats, the apparent digestibilities of the total protein, fat, sugar, and total solids of fresh whole milk, spray process powdered whole milk, and roller process powdered whole milk. No significant differences in the apparent digestibility of the two kinds of powdered milk were found.

The apparent digestibility of the protein of fresh whole milk was significantly higher than that of powdered whole milk. The fat of both fresh whole milk and powdered whole milk was found to be about 99 per cent digestible, while

the sugar of both kinds of milk was completely digestible.

The detection of reconstituted milk and cream is difficult, as the tests presently used have not proved conclusive. The possible destruction of part of the vitamin content, the extent of which depends upon methods used for concentrating the raw milk product, and reconstituting, is not sufficient to serve as a basis for characterizing milk as having been reconstituted. Perhaps most significant are the properties of the precipitated curd with adherence of part of the natural lactose to the curd in such a way that it cannot be readily washed out. The latter is stated to be the basis for the Evenson test.¹⁵ Some slight differences have been reported in the protein constituents of milk caused by concentration, but these are not considered sufficient for detecting the presence of reconstituted milk in fluid milk.

Although milk can be reconstituted in such a way as to comply with the usual chemical and physical tests for added water in fluid whole milk, it may show the presence of added water when analyzed by the usual methods for determining added water in fluid milk, if it is not properly reconstituted.

W. H. King has been appointed associate referee in the Association of Official Agricultural Chemists, to study the chemistry of reconstituted milk, particularly with reference to chemical tests. In his first report, at the October, 1946, meeting of the Association at Washington, D. C., he stated that there is need for improvement in methods which have been used to detect the presence of reconstituted milk by objective chemical tests. Further investigation is planned of present tests and other chemical approaches to the problem.

It appears that the use of reconstituted milk will be largely confined to those tropical or sub-tropical areas where the local supply of fluid milk does not meet the demand. This is not only

TABLE 1

State Regulations Governing Sale of Reconstituted Milk

<i>Illegal</i>	<i>U.S.P.H.S. Milk Ordinance and Code</i>	<i>State Enforcement through Local Ordinances</i>	<i>State Milk Ordinance</i>	<i>No State Regulations</i>	<i>Unclassified</i>

			Wyoming		

true of some of the southern states of the United States but applies also to certain foreign countries.

At the present time, several southern cities are using reconstituted milk as an adjunct to their fluid milk supply. Plans are being formulated by the Department of Agriculture to try out reconstituted milk prepared from powdered milk in 16 schools—4 each in Louisiana, Mississippi, Georgia, and South Carolina. The reconstituted milk will be used not only in the preparation of cooked dishes, but converted into a beverage that looks exactly like bottled milk. The experiment will be closely watched and records kept of which dishes the children liked best, and how well they drink the dry-milk- and water beverage.

Mexico City has just started the use of reconstituted milk on a large basis. The dry milk is obtained from manufacturers in the United States, reconstituted and pasteurized in Mexico City and distributed in wax paper containers.

SUMMARY

The legal, bacteriological, sanitary, chemical, nutritional, and analytical aspects of reconstituted milk are presented.

Information received from 42 states covering regulations governing the sale of reconstituted milk show great variation, as given in Table 1.

It seems apparent that the use of reconstituted milk, to supplement natural fluid milk, is increasing in various parts of the world.

The study of reconstituted milk should be continued, particularly with the view of establishing bacteriological, chemical, biological, and sanitary standards for this product.

What Is a Public Health Engineer or a Sanitarian?

That question is answered for New York State by a recent addition to Chapter XI, "Qualifications for Public Health Personnel," of the New York State Sanitary Code. The recent addition is known as "Section G" and is entitled, "Public Health Engineers, Sanitarians, Sanitary Inspectors."

The public health engineer is described as that individual with professional training and experience in engineering, plus specialized training in the application of his engineering knowledge and skills to public health.

The sanitarian is listed as the person who, through training and experience, is qualified for membership in a scientific profession and with specialized training in methods and techniques utilized for the protection and promotion of the public health through control of the environment. "Activities related to the control of milk, food, or other phases

of environmental sanitation not involving public health engineering" are given as examples of duties.

The sanitary inspector is classified as the subprofessional individual.

The Code Amendment goes on to require all appointing authorities to employ only those public health engineers, sanitarians, or sanitary inspectors who can show satisfactory evidence of possessing the minimum requirements as established by the Amendment. Five grades of engineers are outlined, giving typical duties and required training and experience necessary for each grade. Three grades of sanitarians are described in a similar manner. There is only one grade of sanitary inspector provided for.

The Amendment referred to above appears in a *Health News Supplement* for June 30, 1947 published by the New York State Department of Health, Albany.

Safe and Beneficial Utilization of Nuclear Energy*

ANDREW H. DOWDY, M.D.

Professor of Radiology, School of Medicine and Dentistry, University of Rochester, Rochester, N. Y.

THE last half century has seen more scientific advances than any similar period in the history of civilization. Acceleration of discoveries and inventions, and their application to applied science have been most noticeable in the past fourteen years. There is a variable but unavoidable lag phase between the acquisition of any new scientific fact and its application to a practical use. The shorter this lag phase the more rapidly will civilization progress. Scientists in coöperation with industry have an unprecedented opportunity to develop the safe production and utilization of nuclear energy for peacetime uses. One can scarcely conceive of a basic science which is not essential to the full realization of this objective. The medical profession and the specialty of industrial hygiene are destined to play important roles.

It is human nature to emphasize the dangers of recently developed powerful agents and to lose sight of their probable usefulness. It is not unlikely that prehistoric man was introduced to fire as a naturally occurring result of lightning having ignited some object or objects in his environment. His immediate concept of fire, doubtless, was that of a most dangerous and destructive agent. The first ingenious and courageous man who was able artificially to produce and control fire must indeed have gained

both the envy and the distrust of both friend and foe. With the advance of civilization, fire has remained an ever potential hazard. Yet its beneficial uses have been so developed and utilized that at present it is one of the essential agents of modern civilization. The evolution of controlled nuclear energy can and must bring this new source of power to a similar esteem in the eyes of the civilized world.

With the discovery of nuclear fission and the production of nuclear energy on a large scale, the old hypothesis that matter is indestructible is no longer tenable. It is possible to convert mass into energy and the latter may be dissipated in the performance of useful work or at a complete loss into the surrounding atmosphere. Einstein's equation $E=mc^2$ where E represents energy in ergs, m denotes mass in grams, and c equals the speed of light in centimeters per second, represents the energy possible were there a complete conversion of mass into energy. One must hasten to emphasize that such a complete conversion of any particular mass is impossible even with uranium 235 or plutonium. It is possible to convert only a very small per cent of the mass of these substances into energy. In the case of uranium 235 the ratio of mass lost by fission to the original mass is approximately one-tenth of one per cent. The best known yield of conversion of mass into energy is in the sun where it is approximately one per cent. This does not mean that there is not an enormous

* Presented before the Industrial Hygiene and Public Health Nursing Sections of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946

amount of power made available by the conversion of mass into energy. One kilogram of uranium 235 in undergoing fission loses one gram of mass and releases 25,000,000 kilowatt hours of energy.

While there is a vast quantity of potential nuclear energy, which may be released from a naturally abundant metal such as uranium, there are certain aspects relative to its production on a commercial basis which at the present prohibits its competition with the energies derived from the combustion of oil, gas, and coal. This does not mean that in the near future the situation may not be reversed. There are many scientific purposes to which the products of controlled nuclear energy are being put at this time. We are concerned with the hazards of production of nuclear energy and the immediate utilization of its products.

RADIATION HAZARDS OF PRODUCTION

Uranium occurs in nature admixed with small amounts of radium. During the separation and purification of the crude uranium ore there is a possible human exposure to external radiation from alpha and beta particles and gamma rays. Radiation may arise from an external or internal source. The latter results from radioactive dusts, gases, or solutions which have gained access to the interior of the body through absorption by the skin, the lungs, or the gastrointestinal tract.

The neutron is a type of radiant energy particulate in character, neutral in charge, and derived from the nucleus of the uranium 235 atom when it undergoes fission. During the process of fission the uranium atom breaks into two fragments known as fission fragments. These vary in size, chemical composition and degree of radioactivity: some are gases, others solids. In general, those in the ascendancy have approximately one-half the atomic weight of the original uran-

ium 235 atom. A neutron from a uranium 235 atom undergoing fission may be captured by an atom of uranium 238 which in turn transmutes into the radioactive element plutonium. Many other elements contained in the pile as impurities may likewise capture a neutron and transmute into radioactive isotopes. From this it is seen that two different types of radioactive isotopes are formed in the pile, one by fission of uranium 235, and the other by neutron capture. Neutron capture also may give rise to the release of radiant energy in the form of gamma rays. The isotopes, formed as a by-product of the pile, may emit beta particles, gamma rays, or both. The pile thus becomes a radiating source for large amounts of potentially dangerous radiant energy.

Gamma rays and neutrons are important as the primary hazards from external radiation. Both are extremely penetrating and capable of producing profound and harmful biological changes. Injury may result from external beta radiation in which damage is usually confined to the skin. It is doubtful if external radiation from alpha particles presents any hazard because of their poor penetrating ability, most of them being stopped by the clothing or the superficial layers of the skin.

Alpha, beta, and gamma radiations may result in serious damage once their parent source gains access to the interior of the body (internal radiation), through skin absorption, inhalation, or ingestion. The resultant injury is largely independent of the route of entry but directly dependent upon the type or character of the radioactive material, its distribution within the body, its storage, its rate of excretion, its half-life, and the amount of material involved. The toxicity of uranium *per se*, because of its low radioactivity, is chemical in nature and will be discussed later. The reverse is true of radium and the many radioactive fission products and isotopes.

Radium stored in the body can be detected by the presence of its gaseous decay product, radon. The presence of radium within the body in no way alters or changes its rate of decay. The gaseous radon establishes an equilibrium with the amount of radium contained within the body and is partially absorbed by the circulating blood and carried to the lungs where it is liberated with the expired air. A measurement of the amount of radon in the expired air of an individual is an index of the amount of radium contained in the body of that individual. The amount of radium which can be tolerated in the body because of its low rate of excretion, its high degree of radioactivity, and its long half-life (1590 years), is extremely small and has been considered to be not more than one-tenth (0.1) of a microgram.

All living cells whether of man, animal, or plant, are capable of injury from these various types of radiant energy. The extent, location, and type of injury which may be sustained, are dependent upon the kind of radiation under consideration, its physical properties, mode of application (whether external or internal), intensity, duration of exposure, and the character and function of the cells of the species of animal or plant being subjected to irradiation. In other words, the degree and character of the biological changes resulting from irradiation are dependent upon many complicating factors and often subject to difficulties of interpretation.

Many important contributions to radiation biology have been made by the various laboratory groups working on the health protection aspects of the atomic bomb. These findings are now being evaluated and written for publication in the not too distant future. The *modus operandi* of irradiation upon biological tissue and body systems is not thoroughly understood and requires much additional study. When this mechanism is known, we will probably have a much better

understanding of the mysteries of life.

In man the most sensitive tissues are the reproductive cells of the generative and hematopoietic systems. These are the systems which will be first noticeably effected by chronic exposure to suitable types of radiation. In certain types of laboratory animals, namely, mice and fruit flies, the genetic mechanism is known to be susceptible to damage at relatively low dosages. In each instance the probability of an injury, and its degree, is dependent upon the character of the radiant energy, its intensity and duration, and the frequency of exposure. The reproductive function may be temporarily decreased, interrupted, or permanent sterility may ensue. The circulating leucocytes and erythrocytes may be unaffected, slightly decreased, or depleted. As the degree of injury on the hematopoietic system increases, a profound leucopenia may result followed by a reduction in the number of platelets and red blood cells with a concomitant fall in the hemoglobin. Should the amount of the irradiation be sufficient, the animal or individual may manifest cutaneous, subcutaneous and internal hemorrhages with bleeding from the body orifices. These latter indicate extensive injury and the individual may succumb from secondary infection. The bone marrow and lymph nodes in such instances may reveal almost complete destruction. Such a disastrous result may eventuate from repeated chronic irradiation or from a single exposure as experienced by the people of Hiroshima and Nagasaki and the test animals at Bikini. It is not improbable that animals and humans thus exposed but not succumbing may at a future date show an increased incidence of leukemia as compared with an unirradiated but otherwise comparable group.

CHEMICAL HAZARDS OF PRODUCTION
Chemical hazards are present during

certain phases of the production of nuclear energy. Here we are principally concerned with the toxicity of uranium and its multiplicity of compounds including the fluorides. Although uranium is a weakly radioactive substance (alpha emitter), this particular property as such is of no practical importance as a radiation hazard in comparison with its chemical toxicity. Its detection in body excreta, therefore, generally depends upon its chemical rather than upon its radioactive properties. One of the first problems of the health groups was to develop a reliable quantitative method for its detection in very small amounts. A method was developed which enables one to measure accurately one part in 10,000,000 in animal tissue, blood, or urine. Its presence can be detected in much smaller amounts, $1/2,000,000,000$ of a gram.

To a limited degree, the toxicity of uranium varies with the solubility of the compounds. The various compounds may be encountered in the form of particulate dusts or gases. Protection against chemically toxic dusts and gases is an old problem to industrial engineers, toxicologists, and industrial hygienists. Protection consists in completely closed systems where possible, adequate circulation systems to evacuate the deleterious agents from the atmosphere, gas masks, and special procedures for laundering the work clothing of plant workers. Personnel hygiene and rigid medical supervision to detect small amounts of noxious substances in excreta are important features of adequate health protection. Such a program requires that industrial physicians be conversant with the clinical abnormalities likely to result from undue exposure to the chemical involved. The production of the atomic bomb and the peacetime utilization of nuclear energy and its products have and will require the utmost in coöperation between industry, industrial hygienists, radiobiol-

ogists, toxicologists, and scientists in general.

The toxicology of uranium and its various compounds has been the subject of a very thorough and careful investigation. It is doubtful that any other industrially hazardous chemical has had a comparable investigation in such a brief time. The results of these studies carried on by the several medical groups are being assembled for publication. It is sufficient to state at this time that many of the uranium compounds may be absorbed into the body through the skin, by way of the lungs, or from the gastrointestinal tract by ingestion. Uranium *per se* is primarily a nephrotoxic substance and is principally excreted through the kidneys.

Despite the urgencies of war, the operation of the Manhattan Project resulted in an enviable safety record for the undertaking as a whole. The hazards which have been enumerated can be circumvented. In the conversion of this new industry to peacetime pursuits, there must be no relaxation of protective measures.

THE BENEFITS OF NUCLEAR ENERGY AND ITS PRODUCTS

The possible benefits to be derived from the peacetime utilization of nuclear energy and its products present to the scientists a situation almost comparable to a Utopia. Certainly 20 years ago, today's scientific and pseudo-scientific thoughts would have been classed as the dreams of a madman, to wit, stratosphere rockets, man-made meteorites, or possibly a celestial body, radio-controlled, nucleo-powered cargo planes, uranium powered ocean going ships capable of crossing and recrossing the ocean on the energy derived from the conversion of one gram of mass to energy.

Various multi-million dollar regional experimental laboratories are being established for further research on development and utilization of nuclear energy.

Large-scale projects range from stationary power plants to mobile plants for the propulsion of battleships and submarines. The not too distant future of these projects would seem to be hopeful.

The products of nuclear energy for peacetime purposes have been available since late summer of 1946. To stimulate and encourage fundamental research in medicine, biology, chemistry, physics, and other sciences, the Manhattan District at Oak Ridge, Tenn., developed a program for the production and distribution of radioactive isotopes on a national scale. The first eleven months following V-J Day were spent in the conversion of the pile to isotope production, procuring of personnel, and the setting up of an organization for the equitable distribution of the isotopes. Major General Groves appointed an Interim Advisory Committee on Isotope Distribution Policy and two advisory subcommittees, one on Allocation and Distribution, and one on Human Applications. The advisory committees were to operate in conjunction with Dr. Paul Aebersold, Chief, Isotopes Branch, Research Division, U. S. Engineer Office, Manhattan District, Oak Ridge, Tenn.

The success of this program may be measured by the following accomplishments. More than 50 radioactive isotopes are being produced by the uranium pile through neutron irradiation and fission processes for national distribution. Between July 1 and September 30 of this year more than 150 applications for isotopes have been received and processed. The vast majority of these applications have been approved. Thirty-eight or more of the requests have been for C 14. Within the coming year it is anticipated that the production of C 14 will be sufficient to supply the needs of most research workers presenting worthwhile problems. It seems likely that the limiting factor in distribution in the near future may well be the lack of in-

struments and well trained personnel for the utilization of the available isotopes.

Prior to the war many of these isotopes were known and made in small quantities by cyclotrons. While the quantities available by cyclotron production were relatively small and limited in experimental utilization to a few centers, sufficient information has been obtained to establish their importance as an investigative tool and possible therapeutic agent.

A note of warning should be sounded in reference to the value of these radioactive isotopes as therapeutic agents. The *most important* and *immediate* value will be as an investigative tool. This does not mean that important therapeutic uses will not and are not being made of certain radioactive isotopes at the present, but the public must not expect them to furnish an *immediate* cure for cancer. Many secrets remain to be pried from the isolated cell and the organism as a whole relative to their metabolism and physiology under normal and pathological states. The attack on cancer, therefore, must be both a direct and indirect one.

The radioactive isotope C 14 seems likely to become one of the most important that will be utilized as a tool. Carbon is the one element which is common to all organic compounds. Carbon, hydrogen, and oxygen, plus chlorophyll and the sun's rays are responsible for a vast source of energy in the form of carbohydrates. Under the conditions of extreme heat and pressure that exist in the sun, hydrogen is converted into helium with the liberation of tremendous amounts of energy. It seems likely that C 14 and H 3 have an obvious destiny in the hands of well trained scientists in helping to reveal many of nature's secrets. There are many other radioactive isotopes which are or will prove important but time and space permit the mentioning of only a very few, such

as, sulfur, iodine, potassium, hydrogen, iron, arsenic, sodium, and phosphorus.

Should no advantage other than the quantity production of a large number of isotopes accrue from the Manhattan Project, the expenditure of \$2,000,000,000 will eventually be repaid many times over in the years to come from increased commercial production and better health to the nation.

A great deal of fundamental investigation by various groups in the country has been done with radioactive iron to study anemic states and the formation of hemoglobin, and the body's reserve of iron. The body needs for potassium and sodium have been studied by the use of radioactive isotopes of these elements. Radioactive phosphorus is potentially a useful agent for the treatment of polycythemia and the leukemias. Radioactive iodine seems promising in the treatment of selected cases of hyperthyroidism and a certain small percentage of cancers of the thyroid. The general public must be neither over-optimistic nor pessimistic but should be hopeful. It will require some time before the efficacy of radioactive iodine for the treatment of hyperthyroidism can be evaluated in comparison with the surgical care of such cases. Its use in certain types of cancer of the thyroid would seem to be more rational for the treatment of malignancy than is the use of phosphorus in leukemias. But again, it must be emphasized that cancer of the thyroid is infrequent in comparison with cancer in general, and of the total thyroid cancers only a very small per cent retain the ability to absorb and retain sufficient amounts of radio-

active iodine to be of therapeutic value.

Without a doubt many scientists in the next few years will strive to find or synthesize chemicals having a toxicity for certain cancer cells and a high predilection of absorption by these same cells in contrast to the cells of the normal body tissues. Should such a compound be discovered the next logical step would be to select a radioactive isotope having the proper half-life and energy values and synthesize it into the compound. By so doing the cancer could be attacked both by a chemical toxin and an internal radiation limited primarily to the site or sites involved by the cancer tissue. Such a possibility is not an idle dream but its realization may be delayed.

The real solution for the cancer problem does not lie in its surgical and radiation treatment. It lies rather in discovering the fundamental principle or principles wherein a healthy cell escapes its normal growth restraints and disregards its function as a serviceable unit of an organized whole.

SUMMARY

We have briefly reviewed the possible dangers in what is potentially the most hazardous industrial process known to man. It has been pointed out that the hazards were circumvented during the wartime. There can and must be a safe peacetime production and utilization. The commercial and scientific benefits are multitudinous. The program for the national distribution of radioactive isotopes is well under way and from this single feature alone will come many new scientific facts which will be of inestimable benefit to us all.

The American Academy of Pediatrics Study of Child Health Services: Results to Date*

Washington, D. C.; Director, American Academy of Pediatrics Study of
Child-Health Services, Washington, D. C.; and Surgeon, U. S. Public
Health Service, Washington, D. C.*

IN November, 1944, when the American Academy of Pediatrics committed itself to undertake a nation-wide study of child health services, it is doubtful whether anyone realized the true significance or the magnitude of the step which had been taken. The recognition by an organized group of medical practitioners of their responsibility for informing themselves, through their own labors, about medical care matters, as well as their realization of the need for assistance from public agencies experienced in such undertakings, has produced a coöperative enterprise which is unique in many respects.

Simply stated, the objective of the study is to gather information on the present status of child health services in this country to be used as a basis for future planning. In accordance with this stated objective, the Academy, with the assistance of the U. S. Public Health Service, and the U. S. Children's Bureau, has developed a program

through which the facts concerning existing facilities and services for child health may be made available to all groups, public and private, national and local, for use in furthering programs for child health.

The most immediate as well as the most rewarding results of the study to date have been the development of a spirit of coöperative enterprise and the evident stimulation of interest among members of the medical profession. The almost universal demand on the part of the various states that the statistical material be returned to them as quickly as possible indicates both the great interest which the study has aroused and the apparent need for such a project at the present time. This increasing state and local interest has emphasized the importance of returning quickly to the states, information basic to local planning.

The difficulties anticipated in trying to secure adequate finances and personnel for the study have not proved as great as was feared. All but two states are conducting study programs, and these two are expected to get under way shortly. State programs have been financed from a variety of sources,

* Condensed from a paper read by Katherine Bain, M.D., at Joint Session of the Maternal and Child Health Section and the School Health Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

such as local chapters of the National Foundation for Infantile Paralysis, state departments of health, medical societies, tuberculosis organizations, local foundations, and other sources. Space, equipment, and clerical assistance, as well as funds, have been provided by many agencies, notably health departments.

Qualified personnel for the conduct of the study have not been as difficult to find as was anticipated. Of the 57 executive secretaries employed by all states, 33 are physicians of whom 29 are pediatricians. As of November 1, 1946, 5 states had completed their studies and had delivered their schedules to the central office for tabulation of the data; 11 states had completed the collection of the data, and 14 others were nearing completion. Surprisingly good returns on the schedules have been secured, with some states obtaining 100 per cent returns from pediatricians, and as high as 75 per cent returns for all physicians in private practice.

As the collection of the data nears completion, the question arises—What sort of information will be forthcoming from this study? Although a study of this type cannot answer the specific question—"How many children did not receive adequate medical care in a given year?" it can and will provide much valuable information concerning such items as the proportion of care rendered children by general practitioners as compared to the proportion given by specialists; the amount and type of pediatric training received by physicians who are caring for children; the proportion of visits to children for purposes of health supervision; the number of children admitted to hospitals annually; and the number of children who attend schools which have some sort of school health program.

Data on these and other items will be forthcoming shortly from the North Carolina study which has served as the

pilot study for the entire program. The North Carolina study, begun about a year ago, has been the pilot not only for methods of organization and the content and wording of the schedules but for the methods of analysis as well. Revisions of the original schedules have necessitated many revisits in North Carolina, but the data for that state are now coded, the cards punched, and the tables are being prepared. Soon after January 1, 1947, a complete report will be available from North Carolina which can serve as a guide for other state reports.

The following brief discussion of some of the material obtained in North Carolina will serve to indicate the type of information which will be available from this and other states in much more detail. The original list of physicians compiled for North Carolina contained 2,079 names. To each of these was sent a letter with the appropriate schedule (III-A) attached. Subsequent information concerning physicians who had died, moved, or were not in active practice, reduced this list to 1,571 physicians in active private practice. Of this number, 1,105 filled out a schedule completely or in part, a rate of coöperation of 70 per cent. In order to determine the difference in coöperation among the various age groups of physicians, a single item on the schedule, the completion of a one day record of child visits, was selected as the index of coöperation. A total of 966 physicians completed this part of the schedule (see Table 1). Coöperation was best in the younger groups, a little less than 75 per cent response having been received from the age groups under 45. For physicians over 65, the response was only 50 per cent. Perhaps younger physicians are more interested in problems of medical care, or perhaps the older physicians have become resistant, through long exposure, to the questionnaire method.

One question which the study pro-

TABLE 1

Physicians in Private Practice Who Reported Number of Child Visits during One Day, by Age of Physicians. North Carolina, Spring, 1946

	Total	Under 45	45-64	65 or Over
1. Total in North Carolina in private practice	1,571	536	817	218
2. Number who reported child visits	966	395	463	108
3. Per cent who reported child visits	61	74	57	50

poses to answer is, "Who takes care of the children?" Admittedly pediatricians are so few in number that if children are receiving care they must be getting it from general practitioners. What proportion then of visits made by general practitioners is for children? The average number of visits per day per general practitioner in North Carolina was 25. This figure includes patients seen in office, hospital, or patient's home. Of these 25 visits, one-third were for persons under 15 years of age (see Table 2). The pediatricians' figure for total visits per day was 26, very close to that of the general practitioner. Ninety-nine per cent of the pediatricians' visits were to children.

The figure of 25 visits per day per general practitioner was of considerable interest. The study was made in May

and June in North Carolina when low illness rates might be expected. Sundays, holidays, and days off were all included. The range of total visits for all physicians was quite wide. Eight per cent of the general practitioners made no visits on the report day, while 9 per cent made more than 50 visits. This sample of 558 general practitioners in North Carolina may be too small for reliable conclusions. The returns on this item from other states are awaited with interest.

If the general practitioner is giving so much of his time to child patients, is he seeing sick children or is he devoting a share of his time to health supervision of well infants and children comparable to the time given to this activity by the pediatricians (see Table 3)? Of home, hospital, and office visits to children made by pediatricians, 35 per cent, or

TABLE 2

Number of Total Visits and Child Visits per Day per Physician: General Practitioners, Pediatricians, and Other Specialists. North Carolina, Spring, 1946

	General Practitioners	Pediatricians	Other Specialists
1. Number of total visits per day per physician	24.7	25.5	20.1
2. Number of child visits per day per physician *	8.5	25.2	3.2
3. Per cent of total visits which were for children	34%	99%	16%
4. Number of physicians reporting	558	39	236

* Children under 15 years of age

Number and Per cent of Child Visits in One Day Which Are for Health Supervision: General Practitioners and Pediatricians. North Carolina, Spring, 1946

	General Practitioners	Pediatricians
1. Number of child visits per day per physician *	8.1	25.2
2. Number of child visits for health supervision per day per physician	1.6	8.7
3. Per cent of child visits which are for health supervision †	20%	35%
4. Number of physicians reporting	624	39

* Children under 15 years of age

† Well children seen for health examinations, immunization, advice on feeding, and so forth

1 in 3 visits, were for well children. The comparable figure for the general practitioner was 20 per cent, or 1 visit in 5. The exact nature of this health supervision is not known. Many of the visits may have been for immunization alone. Further analysis may show that the general practitioner's practice is heavily weighted by visits to infants under 1 month, since obstetrics is largely in the hands of the general practitioner. Nevertheless, these preliminary figures indicate that the general practitioner plays a large role in health supervision.

What about the relative amount of child health supervision given by private practitioners and by medical well child conferences? To make such a comparison, certain adjustments in the figures must be made. Since the age groups served should be comparable, only child health supervision visits to children 1 month through 5 years by private practitioners have been included. Because the returns from well child conferences represent all the service in the state, the physicians' returns have been adjusted to 100 per cent (see Table 4). In North Carolina about .7 times as many visits for health supervision of infants and preschool children take place in the physicians' offices as occur in well child conferences. The general practitioner is doing about 4 times as much of this work as the pediatrician. Stated in another way: Of the visits for health supervision for the age group 1

month to 6 years, 71 per cent are made to general practitioners, 16 per cent to pediatricians, and 13 per cent to child health conferences. The actual load of the general practitioner is heavier still, for from a preliminary review of the Series II schedules, it is apparent that in North Carolina the general practitioner is an active participant in child health conferences.

One might go on from here to ask a number of other questions. How are the general practitioners trained in pediatrics? Within the last few years there has been great emphasis on growth and development and on behavior problems in the training of pediatricians. To what extent have these fields become a part of the training of the general practitioner? One section of the study is directed toward answering these and other questions on medical education. The study of pediatric education is just starting, a pilot study having been undertaken at the University of Michigan Medical School in October, 1946. During the current academic year all medical schools and teaching hospitals in the United States will be studied intensively regarding undergraduate training and specialty training in pediatrics.

Though results of the Academy study in the form of statistical tables are meager at present, other less specific results point to a substantially significant trend. Coöperation in a common

TABLE 4

Total Volume of Health Supervision for Children Aged 1 Month to 6 Years, in One Day: Private Practitioners and Well Child Conferences. North Carolina, Spring, 1946

Child visits for health supervision.....	Total	Number	Per cent
		1,330	100
By physicians		1,158	87
General practitioners		948	71
Pediatricians		210	16
To well child conferences (one day) *		172	13

* Total visits 62,859 divided by 365

venture has been undertaken and has been successfully carried out between a private organization of physicians and two federal agencies. Interest of the physicians themselves has been captured. Many pediatricians who coöperated at first from a sense of duty, are now vitally interested and are making extensive plans for use of the material in their own states.

Although the immediate task has been limited to the collection and analysis of the facts concerning current child health services, it is apparent to all that this task constitutes only the first step toward the achievement of the ultimate

goal—the development of an adequate program of health and medical care for all children. To the members of the study staff who have been closely involved in the conduct of the study, the successful development of this spirit of coöperative enterprise and the evident stimulation of interest among members of our own profession have been the most significant and the most encouraging results of the study to date. All indications now point to a growing realization of the next step as a logical outcome of the present activities: the development of an action program to improve health services for children.

National Hearing Week

The American Hearing Society announces National Hearing Week, November 9–15. In this campaign to focus public attention on the hearing, it is joined by its 120 local chapters throughout the states. Nearly 3,000,000

children and nearly one out of every ten persons in America have a hearing loss.

For details of the National Hearing Week, write the American Hearing Society, 1537–35th Street, N.W., Washington 7, D. C.

The Value of Industrial Hygiene^{*}

T. LYLE HAZLETT, M.D., F.A.C.P., F.A.P.H.A.

Medical Director, Westinghouse Electric Corporation, Pittsburgh, Pa.

HYGIENE is a branch of medical science that relates to the preservation of health. This definition outlines the scope to which our thinking should be carried when we evaluate the effects that may result from the coördination of the many sciences that are contributing to the well-being of our industrial population.

Since the main objective is prevention of illness from the occupational environment, the medical profession must accept the responsibility and be the guiding spirit in realizing this objective.

The effects of any agent on the human body must of necessity be studied with regard to the normal physiological actions as well as the abnormal. This dual concept is fundamental in medical science. While the medical phase may play a dominant part in our evaluation of the worth of industrial hygiene there are three other distinct elements: engineering, chemistry, and physics, all of which must be closely correlated if we are to attain our objective.

Industrial management has at times overlooked the value of controlling industrial environment, not only from a purely economic basis but also from the point of view of the psychological reactions of the individual worker. This fact has been emphasized more recently by the increased interest shown in the matter by our organized labor groups which were keenly aware of the psychological factor in spurring the production reached during the period of World War II.

Perhaps the greatest advance made during the recent war years has been the attempt to analyze individual jobs in respect to the physical and mental requirements. This job analysis made it necessary not only to study the physical effort necessary for the job but also the chemistry of the materials involved in the job. Furthermore, the engineering aspects of the machine and its functional operation in its relation to the individual who has the responsibility of operation has elicited extensive study.

Much still remains to be done in this matter of relation of the worker to the job. It definitely is a phase of industrial hygiene in its broadest conception.

Since 1915 much has been accomplished by our efforts in accident prevention in our industrial plants. These efforts were based on the theory that all accidents can be attributed to mechanical failure. The human element, which perhaps is a factor of failure in 80 per cent of our industrial accidents, has been entirely neglected. In view of the broadening vision that industrial well-being is an asset in any accident prevention program to render it of real value, there must of necessity be an equal interest in and a study of the human element in its relation to the mechanical causes of all industrial injuries. This requires the close coördination of industrial hygiene personnel and those responsible for safe mechanical working conditions. With such an organization we will enter a new era in our efforts to reduce the enormous toll of accidents in industry. According to

^{*} Address of the Chairman, presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

statistics of the National Safety Council for the year 1945 there were 16,000 fatalities, 80,000 permanent disabilities, and 104,000 temporary disabilities charged to industry. This constituted a man-day loss to industrial production of 46,000,000 days—a loss which cannot be estimated in monetary value.

The working population in the United States now numbers approximately 60,000,000 persons, and out of this group there are probably 15,000,000 persons working in those industries which use potentially hazardous materials or processes. In these selected industries, perhaps about one-third of the total persons employed are exposed to some type of material or process which may involve a potential health hazard. These 5,000,000 exposed persons present a very real problem to industry throughout the nation, and the value of industrial hygiene is being demonstrated by the preservation of the health of these people.

During the war years a new viewpoint was developed toward industrial hygiene activities. Many industries suddenly were faced with the problem of protecting the health of thousands of men working with hazardous materials or processes. There was an instantaneous demand for trained personnel, and this demand was filled by drawing persons from related fields of activity in medicine, engineering, chemistry and physics.

One of the outstanding accomplishments in the field of control of occupational diseases during the war period was the work of McConnell, Flinn, and Brandt in government owned ordnance explosive plants. In the 968,000 man-years of operations (among 309,000 operating employees in 101 plants) there were only 28 fatalities because of occupational disease—22 from trinitrotoluene, 3 from nitrous oxide, 2 from carbon tetrachloride, and 1 from ethyl ether—a rate of less than 3 fatalities per 100,000 workers per year. Despite the

magnitude of explosives production, the total of 22 fatalities due to TNT reported here is but a small fraction of the 475 fatalities reported from TNT and related compounds during relatively limited production in World War I. The Army has a commendable record. It established this record even though there was no industrial medical program in the Army in 1941, by using civilian physicians already trained in this field. I am glad to see such results published.

Many industrial organizations have equally commendable records and they too should be published. In fact, I have been amazed at the dearth of such material in our journals. We can be proud of our records, so why not set them down for all to see? Our story in this regard which we all hope to see published soon and which again will show the need for and the value of industrial hygiene is that of the production of the atomic bomb. I am sure all of us, now that part of the story is known, can imagine the magnitude of the task which confronted the physicians, engineers, and physicists at plants engaged in this work. We do not know the whole story as yet, but at least we know industrial hygiene stood the test and was a great factor in the success of this project.

The atomic bomb was a dramatic unveiling of the tremendous power and energy which now can be made available for the benefit of man. It has opened new fields, not only for the possibilities in the generation of power, but it will make available many of the ninety-six known elements in radioactive form. The availability of these radioactive elements will result in many important applications. Perhaps one of the most important applications is their use as tracer elements. Another definite possibility is in their therapeutic application.

The smashing of atoms produces, among other things, tremendous radia-

tion; and the usefulness of the various radioactive elements will be determined to a considerable extent by the emanations which they give off. A challenge is presented to us in this preventive field, and the successful utilization of atomic energy will depend upon the elimination of health hazards associated with the variety of radiations which occur in their use. Electrons, neutrons, alpha particles, gamma rays and other radiations will be included in the field of industrial hygiene as lead and benzol have in the past.

Among examinations of noteworthy effort were those made on workers engaged in the manufacture of insecticide bombs for the armed services. Over half of the bombs produced used a formula containing pyrethrum, sesame oil and freon. Since none of these materials is very toxic to human beings, there was no particular problem of health protection involved. After DDT had been developed and sufficient information was available to indicate that it could be used with safety by personnel of the armed services, a potential hazard was created by continuous eight-hour-per-day exposure among persons performing the various manufacturing operations, and this had to be given serious consideration.

The problem involved not only the possibility of breathing the fine mist produced by the aerosol from the Bug Bombs, but also the possible significance of absorbing DDT through the skin. This hazard was recognized prior to the actual use of this material and, by close coöperation between our industrial hygiene engineers, manufacturing personnel, process and layout engineers, a complete new installation was made with protective measures built in as a part of the original layout of the equipment. Where it was not practical to eliminate the hazard by suitable design and layout of equipment, the hazard was controlled by use of personal pro-

TECTIVE equipment and sanitary measures. Adequate pre-placement and periodic physical examinations were made on all employees involved in this operation. Several months after production was started, certain laboratory findings indicated a need for slightly better control, and such control was established. The production of Bug Bombs has continued into the post-war period, and there have been no cases of illness of occupational disease as a result of these operations.

Another of the high production war items was radar equipment. The manufacture, testing, and operation of the various types of radar equipment involved numerous exposures to high frequency radiation. This type of radiation had been relatively unknown except in the laboratory, and of course there were many suppositions that this radiation might be harmful to human bodies. Some of the common illnesses to which average persons are subject were quickly associated in the workers' minds with this new radiation. Extensive tests and examinations have indicated, however, that these radiations have no harmful effect on persons other than the slight amount of heating which may occur. Usually this heating is negligible and no particular hazard has been demonstrated.

Recently a completely new concept has been established which unites the growing of food, its processing, packaging, and distribution. This close coordination of all these activities at one location has been referred to as "agro-industry." Agriculture and industry have been transmuted into a single integrative activity. This concept of agro-industry is extremely large. It is in fact one of those grand ideas that stagger the imagination with their scope, complexity, and implication. Agro-industry has been applied to the cultivation of cane and root crops, and the manufacture of starch and sugar in

the Everglades of Florida. This concept of agro-industry opens another new field in industrial hygiene.

The impetus given to the study and control of industrial health hazards during the past few years has resulted in a fuller appreciation of the value of industrial hygiene. It is a broadening field and it is now utilizing the services of hundreds of specially trained personnel. The field of industrial hygiene is continuing to draw talent from related professions and it is uniting physicians, chemists, engineers, and physicists in this broad endeavor of safeguarding the health of our industrial workers.

Those of us who are devoting full time to industry and attending the managers' meetings to insure an adequate budget for the current and following years have had it only too thoroughly impressed upon us that the era of "cost plus" is over; things are now different; competition in the price of production is again becoming the paramount issue, and curtailment of expense will be the keynote in every possible phase. This is quite a different story from the one we heard during the war period.

This brings us then to what I feel is an important phase of this discussion concerning the value of industrial hygiene. What are we as physicians doing to preserve the gains made during the war? What have we learned that is going to help us to continue to achieve greater stature among industrialists, the employees, and, last but not least, our own medical profession? It may be presumptuous to suggest the means by which an employer can evaluate his preventive hygiene service. Our experience in large and small plants, however, indicates that management is anxious to have a yardstick by which it can measure the effectiveness of all services. This applies in particular to those who are genuinely interested in the welfare of their workers.

There are tangible profits which may

be shown, such as a reduction in absenteeism, a diminution in the number of grievances presented by individual employees relative to working conditions, the reduction of occupational disease claims, the reduction of actual compensation costs through a reduction in accident frequency, and a reduction in labor turnover. The intangible benefits such as the improvement in general health as the result of periodic physical examinations, and an intensive program of health education can well be included in the estimate of the value of an industrial hygiene program in industry. All of this brings to our attention the necessity of an annual inventory of our work which can be presented to management only if adequate records are kept, and this factor too is of the utmost importance for future programs in the field of industrial health.

In considering the future value of industrial hygiene, one cannot neglect the problems of education. Although limited training now is available in various universities to those who wish to enter the field, there still is need for the establishment of complete courses which will develop workers for the field of industrial hygiene.

We all are familiar with the studies made a number of years ago which indicated that the mortality and morbidity rates among the industrial population were greater than those of the general population. The value of industrial hygiene will be measured in the future by a reduction of the mortality and morbidity rates of industrial workers to the point where they may even be lower than those of the general population.

It is not possible to treat this subject wholly in the time allotted or by a single presentation, but even a brief consideration of our topic suggests the existing challenge to us physicians, engineers, chemists, and physicists upon whom falls the responsibility of safe-

guarding the health of our industrial workers. And, further, it suggests a challenge which presents a new horizon and new frontiers in the field of pre-

ventive medicine in its broad aspects. If we meet this challenge we shall contribute greatly to the continuance of our American Way of Life.

International Tropical Medicine Congress to Meet in Washington, May, 1948

Wilbur A. Sawyer, M.D., Executive Secretary of the State Department's Division of International Congresses, announces the first American meeting of the International Congress of Tropical Medicine and the International Congress on Malaria in Washington next May. The Department of State will sponsor the meeting with the coöperation of five governmental agencies and fifteen scientific societies including the American Public Health Association.

These organizations all have representatives on an Organizing Committee appointed by the Secretary of State with Thomas Parran, M.D., as Chairman, George K. Strode, M.D., and Clarke L. Willard as Vice Chairmen, Rolla E. Dyer, M.D., as Program Director, Wilbur A. Sawyer, M.D., as Executive Secretary, and William L. Breese as Secretary. The representative of the A.P.H.A. on the Organizing Committee is Henry E. Meleney, M.D., who is also Convener of Section XI, Public Health. The scientific meetings will be held in twelve sections: I, Research and Teaching Institutes; II, Tropical Cli-

matology and Physiology; III, Bacterial and Spirochetal Diseases; IV, Virus and Rickettsial Diseases; V, Malaria; VI, Helminthic Diseases; VII, Protozoan Diseases; VIII, Nutritional Diseases in the Tropics; IX, Tropical Dermatology and Mycology; X, Tropical Veterinary Medicine; XI, Public Health; XII, Medical and Veterinary Entomology. There will also be scientific and commercial exhibits and a program of motion pictures on subjects related to tropical medicine. In addition, there will be visits to the laboratories of the Department of Agriculture in Beltsville, to the National Institute of Health in Bethesda, and to other scientific institutions in and around Washington.

Physicians, scientists, and other professional persons qualified in tropical medicine will be enrolled as Members of the Congresses. Those interested are advised to write to the Executive Secretary, Fourth International Congresses on Tropical Medicine and Malaria, Department of State, Washington 25, D. C., for a copy of the Preliminary Announcement with the Advance Registration and Hotel Reservation Form.

Age and Sex Variations in Hospital Utilization*

(An Example of Morbidity Data Available from Blue Cross Records)

J. D. COLMAN, M.E.

Executive Director, Maryland Hospital Service, Inc., Baltimore, Md.

WHETHER a patient did or did not receive hospital care is likely to be governed by his geographic location rather than by the type of condition needing care. However, the practical fact that much data describing serious illness are available from hospital records forces us, at the outset, to accept a compromise with our instincts of precision. Hence we find much morbidity data based on the frequently unbiologic and unpathologic distinction between illness cared for in or out of hospitals. Even in view of the wealth of material available concerning the utilization of hospital care, its usefulness has been materially limited by the difficulty in arriving at any satisfactory description of the population from which these hospital patients came. Thus significant incidence rates expressed in terms of hospital patients per unit of population per year were available only in their crudest form.

The growth of Blue Cross Plans is of interest in this connection because they have the unique advantage of having a known population base. It is possible to, and they do count carefully, the people who comprise their population because it is necessary to collect subscription charges from them. Consequently, we have, for the first time, a large portion of the population whose

use of hospital care is known and whose characteristics as to age, sex, marital status, residence, etc., is known for both that portion of the population that was hospitalized and that portion that was not.

As the proportion of the population enrolled in Blue Cross Plans grows, the likelihood of their enrolled population being materially different from the total population diminishes. The most challenging of the opportunities for study of hospital morbidity offered by Blue Cross data is that which recognizes that, for at least some of our subscribers, the hospital history is continuous over a long period of time. Fifty-six per cent of the participants enrolled in the Baltimore Blue Cross Plan in 1937 are still active subscribers. Very little data of this sort have been developed and it would appear that some important facts would be disclosed from their study. The considerations introduced by the diminishing population base are serious, but do not nullify the value of the study.

As an example of the kind of information which is available from even a simple analysis of Blue Cross records, I present a study of the experience sustained by the Maryland Hospital Service in which its utilization data are classified by the age and sex of the subscribing population. In considering these data, I should remind you that for the most part the experience described was sustained during the war

* Presented before the Vital Statistics Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

years and that only a portion of the obstetrical care used by the population is included herein. Otherwise, however, these data represent a reasonably complete description of the hospital care received by this population in acute general hospitals.

Chart I describes the incidence rate in terms of hospital patients per 100 person-years of exposure—classified by age and sex. From several points of view this is interesting, but much more significant, particularly from the economic standpoint is the data shown in Chart II.

This chart describes the utilization of hospital care in terms of patient days of hospital stay per 100 person-years of exposure—classified by age and sex. The intense variation with age should be of great significance to hospital administrators in planning for the amount of hospital facilities needed in the future in view of the changing age distribution of our population.

It will be noted from the headings on the two previous charts that these described the experience during the entire life of Maryland Hospital Service from November, 1937, to December, 1945. Because of the rapid growth of the subscribing population, most of the exposure supporting these data was sustained during the last three years of this time interval. As one might expect, there have been slight changes during the period which might well be the subject of more exhaustive study.

An indication of these changes is given on Chart III in which age-specific utilization rates, expressed in terms of hospital patients per 100 person-years exposure are shown for the calendar year, 1945, as well as for the entire period, November, 1937, through December, 1945. It is obvious that the frequency of admission has tended to increase at all ages except the 40 through 64 group.

By reference to Chart IV, however,

the effect of crowded hospital facilities is seen. Chart IV presents hospital utilization in terms of patient days per 100 person-years exposure, classified similarly as in Chart III. From this it will be seen that even though the frequency of hospital admissions had increased, the volume of hospital care rendered per unit of population is less during 1945 than for the entire period.

While I have not burdened you with the detailed data supporting these charts, I may say that sufficient exposure supports each point on Charts I and III so that they may be considered statistically significant. I have not yet been able to find my way through the mathematical maze of significance as it applies to a rate expressed in terms of patient days per 100 person-years of exposure. Therefore, I express no opinion on the statistical significance of Charts II and IV, except the "horseback" one that if the rate for patients is significant, the rate based on the days stayed by the same patients from the same population is likely to be.

While some interesting trends are revealed in these data, my purpose in presenting them here is not so much for their intrinsic value but rather to stimulate any of you who have access to Blue Cross records to explore their potentialities more fully as a source of significant morbidity data. The obvious objections of possible selection can, in many cases, be overcome if careful extraction of specific rates is made from which useful adjusted rates can be computed.

Many plans are now using the diagnostic code developed by the U. S. Public Health Service and the Bureau of the Census. The happy fact that a practical Diagnostic Code and a known population came into being at the same time should materially extend our understanding of acute illness. The epidemiology of the acute appendix and the hypertrophied tonsil, if you will!

The People Win for Public Health in Colorado*

FLORENCE R. SABIN, M.D.

Chairman, Subcommittee on Health, Colorado Post-War Planning Committee, Denver, Colo.

TWO years ago the State Government in Colorado had only one interest in its Division of Public Health; namely, that it was one more place in which to try to force political appointments. Moreover, the Denver city machine had had a remarkably successful record in defeating health bills in the legislature. The machine had only to pass the word down the line to kill health bills, and they were killed.

Now, what a change! There is a new Governor, Lee Knous, who campaigned for good government and specifically for a health program, and is enthusiastically carrying out his pledges. On May 20, 1947, an election in Denver brought into office a new Mayor-elect, Quigg Newton, a young man who ran, without benefit of party, against government by political machines. He won more votes than all four other candidates together. He understands the fundamental principles of the movement; he wants, just as eagerly as informed citizens, a modern, professionally staffed health department, and a strengthened medical school for training physicians for both curative and preventive medicine—indeed a true medical center for the Rocky Mountain region. No wonder Coloradoans walk on air and talk of health to match their mountains! They have won the decisive battles of their campaign and now have only to get on with the business of pub-

lic health in Colorado. As a matter of fact, recent history has even more significance than any one cause, however vital, for it has shown that under our American form of government whenever our people really want good government they can have it.

The story of the health program is as follows: In 1945 the Governor of Colorado appointed a Health Committee as part of a post-war planning program and was then persuaded by this committee, by the State Division of Public Health, and the Colorado Public Health Association, to ask for a health survey of the state. By great good fortune, the American Public Health Association was able to undertake a survey through a grant from the Commonwealth Fund, and its Field Director, Dr. Carl E. Buck, came to study conditions.

Dr. Buck made a masterly report. He studied the vital statistics of the State Health Division, analyzed and arranged the data until they told a vivid story of the state's health deficiencies. He found that the State Health Division was badly placed in the government, being a division under the Governor instead of a department, and that it had been subject to repeated attempts at political control. He found that the division had an able director and a small but well chosen professional staff; however, state appropriations were pitifully small—less than 10 cents per person per year—so that the division would have had almost nothing had it not been

* Presented at the Fourteenth Annual Meeting of the Western Branch, American Public Health Association, San Francisco, May 28, 1947.

for generous federal grants; that the City of Denver, by a curious archaic charter, was a so-called "Home Rule City" beyond the reach of modernizing influences from the state; and that of the 63 counties only 4 had full-time health services. Dr. Buck's report revealed the short-comings, pointed out the reasons for them, and made what proved to be expert recommendations for their correction.

Two different types of work were then started, both closely correlated with each other; first, the organization of an executive committee for intensive study of the report and for drawing up the bills to be presented to the legislature; and second, the carrying of Dr. Buck's report and of all the Health Committee's plans as they developed directly to the people of the state.

An executive committee, authorized by the large general committee, had many long conferences. Most of them were at dinner meetings. At each meeting were invited guests who were either representatives of groups that would be affected by the proposed development of health services, or experts who could help with special knowledge and advice. Thus opposition was forestalled in advance. Civil Service Commissioners were also invited to discuss common interests.

One of the outstanding achievements of the program was the full coöperation between the State Medical Society, reaching all the doctors in the state, and the various public health agencies. Two members of the Public Policy Committee of the State Medical Society became members of the Health Committee and made a liaison between the two groups. Common bills were presented to the legislature, jointly drawn and jointly sponsored. Indeed the Medical Society gave up its tax-exempt status and increased its dues that it might support an active lobby.

Another important success in the

health program is that support of the dairy industry was won for health inspection. Like the dairy group in some other states, the group in this state had long feared and fought health inspection of its industry. Many conferences were held with them which were indeed initiated at a luncheon to which they invited the Health Chairman. She was bumptious enough to ask them why they fought the program, and invited them to have a representative on the Health Committee. He gave much help and arranged conferences with members of the Dairy Association, and with all the experts on the subject of milk in Colorado, both from the federal and state groups. Full agreement was reached on the need for higher standards and improved practices for production and for processing of milk and milk products, but the dairy industry wanted to have it designated by law that a dairyman must be on the Board of Health to represent the industry. The Health Committee refused to accept the principle of representation of any group by law. The point was won in the legislature, much to the committee's surprise. The committee was not opposed to the choice of a dairyman for the Board of Health—indeed the Governor appointed both a producer and a processor. Now the State Department of Health and the dairy industry will work together with good will to a common purpose. This is an interesting example of a method of dealing with a controversial issue of long standing; namely, extended discussions to separate the many details on which adjustments can be made from the very few principles, or perhaps only one, too critical for compromise.

When the committee had completed the study of the report and its recommendations, it started to formulate the proposed bills. Fortunately able and experienced legislators and attorneys were members of the committee. It also had the invaluable aid of an attorney,

Hubert Henry, Chairman on Health of the Interim Committee of the Legislature, together with the help of the able secretary of the Legislative Reference Bureau, Clair Sippel. The bills were drawn in advance so that preliminary copies could be sent to the county chairmen and so that they could be introduced early in the session.

The winning of popular support for the program was crucial to its success. Since this was a state program, popular education was started in the counties. Dr. Buck helped to organize the first inter-county meeting. Indeed, every county meeting drew its audience from at least two or more counties. This was always highlighted by definite identification of each county group. It will be remembered that distances are great in Colorado; people drove 75 to 100 miles to meetings. They had been shocked by the complete defeat of the health bills in the last session of the legislature and so were ready to listen. At the early meetings, Dr. Buck with the help of a blackboard, let the facts about the appalling death rates from preventable and controllable disease sink in as the audience listened to the speakers. He showed how essential participation by the audience was to a program.

The committee had no state appropriation for its work but the Division of Health received the approval of Dr. Fred T. Foard, Regional Director of the U. S. Public Health Service, to use federal funds. This, together with a grant from the Colorado State Tuberculosis Association, enabled the committee to have an executive secretary. Herbert Moe organized the meetings and was always able to attract an audience eager to hear the story of Colorado's public health. One member of the committee had wide acquaintance all over the state and was able to find local citizens who could lead their communities. Persons were chosen as individuals rather than as representatives of organizations. At

first each name had to be submitted to the Governor, but he was finally persuaded to give the committee a free hand. Teams recruited from the State Division of Public Health, the medical school, the public health physicians of the public schools, and other groups were provided for each meeting. Dr. Roy L. Cleere, Director of the State Division, took to each county data concerning the local problems, and showed how close should be the coöperation between state and county health services. There were no prepared speeches but new data as developed in the executive committee, were taken to each meeting. A second meeting in a given place always brought the comment, "How your program is growing."

The committee did not itself organize action in any group but merely presented data on conditions, local and state, and showed what public health services could accomplish. Initiation for action was left to the people themselves. As a method, it is the exact opposite to the building of a political machine; it leaves one less sure of results, but with a more lasting foundation. Each local group took up some problem of its own. The first response was in a town where the raw sewage was going into the river and the Mayor soon started a fund for a disposal plant.

In one town the women said that they could see so much dirt in the milk that they did not use it at all. Within a few days the very efficient Supervisor of Nurses and the City Manager of the town with ten women met with the committee in Colorado Springs. El Paso County has an exceptionally efficient milk inspector, really a public health educator—and had developed there a milk supply that is both clean and safe. The group saw a perfectly run dairy—run by a woman, I am pleased to say—and a pasteurizing plant that is the last word in excellence. As a result, the town in question now has good pasteurized

milk shipped in by two companies and a local dairy is putting in a pasteurizing plant. The dairy industry might take notice that public health services are good unpaid advertising agencies, when milk is made both clean and safe. None of the groups did just the same type of work, but all supported the state program and all enjoyed the prestige of working as a Governor's Committee. One group worked politically and reported that all candidates who were against the health movement were defeated and all who were for it elected.

Another phase of the work that has aroused great enthusiasm and rivalry in the state is the federal hospital program. Dr. Foard assigned two members of his staff, Dr. Le Grand Byington and Dr. H. T. Wagner, to make a survey of the hospitals; a medical social worker from the State Division of Public Health, Helen Cannon, visited every hospital to aid in making out the schedules for the Commission on Hospital Care.

As evidence of the interest of the people of Colorado in the health movement, it is now many months since the committee has itself organized a meeting. Rather, every meeting has been on invitation, and speakers have gone to clubs and other groups all over the state. Committee members have spoken, it would seem, to almost every club in the state, both men's clubs and women's clubs. Many of the women's clubs have made the health program their special work for the year; for example, the American Association of University Women and the Parent-Teachers Association in every town where they are organized. In addition, the Women's City Clubs, political clubs, the League of Women Voters, and the Federation of Women's Clubs have all given skilled help. The Chambers of Commerce of the cities have heard about the health program, as well as many Kiwanis and Rotary groups. The Junior Chamber of

Commerce and the Isaac Walton League have actively worked for the program. Groups of lawyers, ministers, college, university, and church groups have been addressed. During the weeks before election the author spoke about twice a day, occasionally three times.

Nor has Denver been neglected, nor have the people of Denver failed to hear of the deficiencies of their so-called Health Department. Both newspapers in Denver, as well as the county papers, and the radio gave unstinted support to the new era in health. After election it was planned to let every legislator hear of the health bills in his home town. The result was summed up in one sentence by one of the prominent legislators who said, "We all knew in advance that this time we had to pass the health bills." The people of Colorado had willed it so.

What bills were introduced? Eight bills in all were presented, each one introduced to the legislature under sponsorship of the committee. There were two groups of bills, five bills setting up services for health and appropriations for them, and three bills for controlling special diseases. The first two bills concerned public health services.

The State Reorganization Bill created a new Department of Public Health, with a Board of Health and an Executive Division. The Board of Health was to be of nine members appointed by the Governor in such manner that no business or professional group would constitute a majority. This concession was made by the doctors. The bill gave to the new department powers adequate to meet its responsibilities in improving the health of the state. Some opposition to this bill developed in the Senate, but only from a certain group of the healing arts, who did not so much oppose the bill, but sought to place riders on it to gain advantages or escape restrictions for their cult. Hard work defeated these proposed amendments. The second

health bill was permissive legislation for facilitating setting up county, city-county and multiple-county health units. Both of these bills passed early in the session. They were well drawn and are worthy of study.

The third bill for appropriations and, as is customary, was presented late in the session with appropriations for all divisions of government. The requests were in two parts—one for the State Department and the other for aiding county units. These bills were given intensive study by the appropriations committee and, though no group obtained all it asked for, the Health Department received funds adequate for great improvement of its services. The grant for state aid to the counties was raised from nothing to \$150,000 for the biennium.

The fourth bill was an enabling act to meet the federal requirements for participating in the new hospital construction program. The fifth bill was an appropriation bill for the medical school. Under the new Dean, Dr. Ward Darley, plans have been developed to stress public health and the training of more general practitioners, rather than specialists. Dr. Darley also plans to have a two or three year residency with the last six months to be taken in the new county hospitals. These plans are an important advance in medical education and the committee was glad to endorse this program.

The three special bills were as follows: two were to lessen incidence of tuberculosis, the third was to decrease Bang's disease in dairy cattle. The bills in regard to tuberculosis were drawn by the State and Denver Tuberculosis Associations and endorsed by the Health Committee. An increase in the per diem allotment to hospitals of from \$4 to \$6 for the care of indigent cases was obtained. It was hoped to obtain money for the construction of a new ward of 100 beds at the Colorado Gen-

eral Hospital under the direction of the Medical School, but support was won for a 30 bed ward only. This will, however, aid in the development of chest surgery in the state, place a number of tuberculosis patients in a general hospital, and help with the training of medical students in this disease. It is a minor gain, to be sure, and indicates hard work ahead during the next session of the legislature.

The so-called Cow Health Bill was the only complete defeat of the committee. It was drawn by a veterinarian on the committee to check the sale of dairy cows that are reactors to Bang's disease. It did not include compulsory testing nor require slaughter, but simply the quarantining and reporting of infected cows. The bill was killed by the livestock interests by having it referred to the Livestock Committee where it was permanently buried. Colorado's important beef and dairy cattle industries make the eradication of Bang's disease unusually difficult. The inter- as well as intra-state shipment and sale of infected animals complicates control measures. This disease is a national problem. Obviously much study must be given to the type of legislation needed, and much research is necessary. How do you account for the fact that a cow may react negatively to the agglutination test and at the same time show a positive blood culture? How effective is calf vaccination? These are some of the questions needing investigation.

The legislature adjourned in April. Already the new State Department of Public Health has been reorganized and strengthened in accordance with modern practices. The department has been asked to help four groups of counties to plan new district health units. This is entirely on the initiative of the counties themselves. These are the first fruits of the program giving the people themselves scope for exercising their own initiative.

One of the meetings was especially interesting. The new law provides that the units are to be set up by vote of the county commissioners. The commissioners of five counties were present. All of those who came from counties where there had been any public health nursing were enthusiastically for the unit. A commissioner from the county that had never had any service said that temperamentally he had to express some opposition against such unanimity of opinion and for his part he was fearfully worried lest swarms of public health workers descend on his county and ask

for jobs. He never knew how funny he was, since the real worry was to find even one public health worker for his county. Personnel is now the major problem in this state as it is everywhere.

All during the war years the now Ex-Governor refused to authorize the use of federal grants allotted to the Division of Health to aid in training public health workers. Thus we have no backlog of personnel; we are developing a training program, but the need is to set up new services now. The people of Colorado are enthusiastically for adequate public health services.

Fourth Interim Health Commission Meets in Geneva

Global health conditions were reviewed by approximately 100 international medical and public health leaders at the Fourth Session of the Interim Commission of the World Health Organization at Geneva Switzerland, August 30 to September 13. These included delegates of the 18 nations on the Interim Commission.

Among the subjects discussed by this session was the World Health Assembly which must be convened within six months after the 26th

United Nations country ratifies the WHO Constitution. To date, 13 UN members have approved the document: China, United Kingdom, Canada, Iran, New Zealand, Syria, Liberia, Ethiopia, Netherlands, Saudi Arabia, Turkey, Union of South Africa, and Norway. In addition, 6 non-members have ratified.

The United States delegate at this session was Thomas Parran, M.D., Surgeon General of the U. S. Public Health Service.

Standards of Dental Care in Public Health Programs for Children*

NORMAN F. GERRIE, D.D.S., M.P.H.

Senior Dental Surgeon, U. S. Public Health Service, Washington, D. C.

AT the present time, the majority of state health programs provide for some type of public health dental activity.¹ Study of these dental programs reveals considerable variation in type and in the features which receive greatest emphasis. The program content has developed as the result of local conditions, expediency, tradition, available funds, and decision by influential persons or groups as to the most effective way of spending funds. Consequently, all states do not conform rigidly to a single type of program. Although it is generally agreed by dental administrators that the objectives of the public health dental program may be accomplished by education, prevention, and treatment, there has been much discussion relative to the potential scope or definition of each of these three basic features of the dental program. Until recently, there was no means whereby prevention of dental disease might be exercised; it is found, therefore, that dental health education and dental treatment service, either alone or together, tend regularly to comprise the principal activities currently conducted as legitimate activities of the dental programs in many states.¹

Dental health education is a prominent feature of dental programs. In some cases it is the exclusive feature. In practice, dental health education of the public by state agencies may extend

from the presentation of simple facts on dental health for the guidance of the individual to an attempt at exposition of the whole field of dentistry as it is known and understood by the dentist.

The term "prevention" has been interpreted frequently as treatment for prevention, particularly in the control of dental caries. Based on this interpretation, provision of treatment was justified as a preventive measure on the grounds that filling of carious teeth would control caries to the extent of preventing undesirable sequelae which would culminate in loss of teeth. Recent developments in the use of fluorine as a true preventive of caries promise methods which will reduce considerably the prevalence of this disease.^{2, 3} Many state dental administrators have indicated a desire to incorporate in their activities, technics for using fluorine as soon as the efficacy of these methods has been conclusively demonstrated.

Although no longer considered a true preventive measure, in the sense that its use will prevent a disease from occurring, at the present time treatment is considered to be an essential part of the dental program. The use of fluorine as a preventive agent is expected to reduce the prevalence of caries by perhaps 40 to 50 per cent. However, there is still a large amount of caries which will occur, necessitating dental treatment by operative procedures for its control. In addition, there are other dental disorders which create a substantial need for dental treatment of various kinds.

* Presented before the Dental Health Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

The wide variation in thought and practice relative to the scope of treatment services in public health dental programs makes it desirable to offer in this presentation an interpretation of the potential range of treatment which might be provided. It is likely that one or more, or perhaps all, of the items to be suggested have been provided at one time or another in various public dental treatment programs. Certainly, in the field of private dental practice they are all considered essential to the health of the individual. The decision that a given item of service is necessary, advisable, or desirable if dental health is to be secured for the individual is directly related to the acceptance of a definition of dental health. The means employed to secure the objectives established by this definition are basic dental health requirements, whether treatment is rendered to the patient in the private dental office or in the public dental clinic. Since the items of treatment presented here have been evaluated for inclusion on the basis of a specific definition of dental health, this definition is offered for consideration.

There are many factors which influence the design of such a definition. It is unlikely that any definition would hold for long because of changes in the science of health and changes in the relative importance of its objectives. It is undesirable that any definition should

be so inflexible that it cannot be adjusted to such changes. On the basis of these considerations, therefore, dental health may be defined as "the objective which the dental profession has in mind in assisting the individual to achieve a satisfactory state of function, comfort, and appearance, provided that his condition has been completely appraised, that he has been informed of existing defects, and that proper treatment has been suggested and made available to him."*

Based on this definition of dental health, and with due allowance for the practical limitations which would necessarily affect any application of the treatments suggested, the following services might then comprise the dental treatment program. They constitute the means by which the objectives of dental health may be secured. It will be noted that the items presented are given as optimal services and also as minimal services. It is expected that the services provided would range upward from minimal to maximal, in accordance with circumstances which might impose limitations on the individual program. In practice, the scope of the dental treatment program would fall at some point between the extremes suggested.

* A modification of a definition of health by Lawrence J. Henderson, Professor of Biochemistry at Harvard University. Prepared by graduate students in public health dentistry, University of Michigan, April, 1946.

DEFINITION OF DENTAL HEALTH TREATMENT SERVICES FOR CHILDREN *

A Statement of Policy:

Considering the present available information on the scope of services required to assure the health of young patients, an oral health program should provide treatment, preventive measures, and health education.

It appears that limitations of treatment services, due to insufficient funds or personnel,

are best applied on the basis of the number of children or age groups to receive care rather than on the number of services or types of treatment to be made available. It seems reasonable, therefore, to provide adequate care for a selected group of children rather than limited services for a large group of children. If dental health programs are developed for the youngest age groups and continuity of care provided thereafter, an accumulation of defects is impossible, and an optimum condition of health, comfort, appearance, and func-

* Based on a statement prepared by graduate students in public health dentistry, University of Michigan, April 1946.

tion would be maintained throughout the period of childhood.

Optimal Dental Services:

*1 Period from Birth Through 2 Years *†*

- a. Surgical treatment by a competent oral surgeon for the cleft lip or palate.
- b. Treatment of mouth infections.
- c. Application of preventive measures for securing and maintaining oral health.
- d. Recommendation or institution of procedures for breaking harmful habits.

2. Period of the Primary Dentition (3-5 years) ‡

- a. Orientation of child to dental environment.
- b. Procedures preliminary to diagnosis:
 - (1) Examination
 - (2) Essential dental records
 - (3) Radiograms as required to detect caries and dental anomalies, and to study development, root-end conditions, and progress of treatment.
- c. Post-operative observation and supervision of the cleft palate patient.
- d. Prophylaxis.
- e. Application of preventive measures for securing and maintaining oral health.
- f. Restoration of carious teeth:
 - (1) Silver amalgam for posterior and anterior teeth.
 - (2) Disking of anterior teeth when incisal angle is involved.
 - (3) Use of cast restorations for broken down molars on the basis of individual diagnosis.
 - (4) Local anesthesia to be used on the basis of individual diagnosis.
 - (5) Cement bases to be used on the basis of individual diagnosis.
- g. Pulp treatment: The pulpotomy technic will be used to manage vital exposed pulps in this period of dentition.
- h. Treatment of mouth infections.
- i. Extractions (type of anesthesia to be determined on the basis of individual diagnosis).
- j. Orthodontic treatment as required.

3 Period of Mixed Dentition (6-12 Years) §

- a. Examination, diagnosis, prophylaxis, post-operative supervision of the cleft palate patient, and application of preventive measures to be the same as for the period of the primary dentition.*
- b. Restoration of carious, hypoplastic, and fractured teeth:
 - (1) Silver amalgam routinely for posterior teeth and primary anterior teeth.
 - (2) Silicate cement routinely for proximal surfaces of permanent anterior teeth.†

- (3) Treatment of fractured permanent anterior teeth.

- (a) Parapical radiograms.
- (b) Pulp test.
- (c) Temporary sedative treatment.
- (d) A substantial restoration such as the $\frac{3}{4}$ crown casting, with window for esthetics.

- (4) The use of cast restorations for hypoplastic or badly broken down permanent teeth that cannot be restored satisfactorily by plastic filling materials.
- (5) The use of cast restorations for broken down primary molars on the basis of individual diagnosis.
- (6) Local anesthesia and cement bases to be used on the basis of individual diagnosis.

c. Pulp treatments:

- (1) Complete treatment for all conditions arising in the permanent anterior teeth, including root resection.
 - (2) Pulpotomy for vital exposed pulps of posterior permanent teeth.
- d. Lost permanent anterior teeth to be replaced by an acrylic palatal plate until a fixed bridge can be placed.
 - e. Lost permanent posterior teeth: The lost tooth or teeth may be replaced by an acrylic restoration, clasps being attached to adjoining teeth.
 - f. Treatment of mouth infections.
 - g. Extractions (Type of anesthesia to be determined on the basis of individual diagnosis).
 - h. Treatment of any condition requiring oral surgery.
 - i. Orthodontic treatment as required.

4. Period of Permanent Dentition (13-17 years) ‡

- a. Examination, diagnosis, post-operative supervision of the cleft palate patient, prophylaxis, and the application of preventive measures to be the same as for the periods of the primary and mixed dentitions.*
- b. Restorations, anesthesia, and bases for carious and injured teeth to be the same as for the period of the mixed dentition.
- c. Lost permanent anterior teeth: Same treatment as for the period of the mixed dentition.

* Orientation of child to dental procedures is to be included if required.

† The use of metallic fillings should be considered for the restoration of the lingual pits of incisors and the distal surfaces of cuspids.

‡ When a thorough diagnosis indicates the need for additional operative procedures, they may be utilized.

d. Lost permanent posterior teeth: Same treatment as for the period of the mixed dentition.

e. Pulp treatments:

- (1) Anterior teeth: Same as for the period of the mixed dentition.
- (2) Posterior teeth: Pulpotomy until approximately the 14th year, the exact age to be determined by the operator through radiograms and other diagnostic aids on an individual basis. Root canal fillings should be inserted routinely wherever and whenever indicated, on individual diagnosis.

f. Treatment of mouth infections.

g. Extractions and surgery: Same as for the mixed dentition period. (Now may include 3rd molars.)

h. Orthodontic treatment as required.

Minimal Dental Services:

It has been suggested that any program of dental care which cannot meet optimal standards should include as a *minimum* the following services:

- (1) Examination and diagnosis.
- (2) Prophylaxis.
- (3) Application of preventive measures.
- (4) Restoration of carious or injured teeth
- (5) Pulp treatment.
- (6) Treatment of gingivitis and mouth infections.
- (7) Extractions.
- (8) Treatment of developmental anomalies of the mouth.

Order of Services:

It has been suggested further that within the group to be provided service, dental care should be rendered in the following order of decreasing emergency, assuming that sufficient examination, diagnosis, and treatment planning has been provided:

- (1) Treatment of all acute or painful conditions of the teeth and severe infections or injuries of the soft and supporting tissues of the mouth.
- (2) Treatment or removal, or both, of infected primary and permanent teeth which have passed the acute or painful stage, and provision of partial pulpectomies for young teeth with vital exposed pulps.
- (3) Treatment of gingivitis or mouth infections which have passed the acute or painful stage.
- (4) Repair of injured permanent teeth and

those permanent teeth attacked by caries.

- (5) Restoration of primary teeth attacked by caries.
- (6) Root surgery for those infected permanent teeth which are of strategic importance to the denture, and in which infection can be eliminated and the root canals hermetically sealed.
- (7) Simple prophylaxis.
- (8) Orthodontic and prosthodontic care for those dentures in which the occlusion interferes with masticatory function seriously, or with the health of the supporting structures, or with the emotional stability of the child.
- (9) Orthodontic supervision for those dentures in which the occlusion presents a serious potential threat to masticatory function, health of the supporting tissues, or emotional stability of the child.
- (10) Provision of treatment for oral anomalies such as cleft lip and palate or mid-line supernumeraries, according to a treatment priority determined by the relative emergency of the condition.

SUMMARY

The evolution of the public health dental program has resulted in general agreement, based on current understanding of objectives and methods, that education, prevention, and treatment shall constitute acceptable phases of the program.

The scope of each of these phases is established in accordance with individual interpretation, policy, and practical limitations.

The definition or potential scope of any phase is directly related to a definition of dental health. A definition of dental health is offered for consideration.

In terms of this definition the items of dental treatment considered essential to accomplish the objectives of dental health are outlined.

Since realistic considerations may limit institution of these items of treatment, a minimal list of treatments is also presented.

A priority for rendition of treatment based on relative exigency is suggested.

Arsenic in Soy Sauce

The San Francisco Department of Public Health, J. C. Geiger, M.D., Director, received notice on July 12 that soy sauce manufactured by a midwest packing company was contaminated with arsenic. According to Dr. Geiger, investigation indicated that much of the contaminated soy sauce had been blended and had reached the local market under various brands, 59 in all. Both retail and wholesale distribution of soy sauce was halted on July 14 and the public was warned of possible dangers. On July 19 the San Francisco laboratory reported studies of 59 known brands, and 32 of them were released for sale. The local press was advised of the names of the brands free of contamination. According to the department, of the contaminated material some of the

specimens contained from 0.06 grains of arsenic per pint (As_2O_3) to as high as 10 grains per pint.

The source of contamination has been traced to a shipment of caustic soda from a chemical weed-killer producer to the soy bean sauce manufacturer through a broker. As soon as the sauce manufacturer heard of the illnesses traced to the soy bean sauce, samples withdrawn at various stages of preparation were analyzed. Samples taken at points following the addition of the caustic soda carried as much as 500 parts per million of arsenic. The manufacturer immediately supplied a complete list of all shipments which might have included the contaminated sauce, thus making it possible to trace suspected lots quickly.

A Method for Assessing the Sanitizing Efficiency of Quaternary Ammonium and Hypochlorite Products*

C. K. JOHNS, Ph.D., F.A.P.H.A.

*Bacteriologist, Division of Bacteriology and Dairy Research, Science Service,
Department of Agriculture, Ottawa, Canada*

THE effectiveness of hypochlorite solutions as sanitizing agents for the washed surfaces of food handling equipment is generally recognized, and these solutions are widely used for this purpose. More recently a number of "surface active" agents of the quaternary ammonium or cationic type have been advertised as substitutes for hypochlorites for this and other purposes. The present studies were undertaken in the hope of throwing some light upon the comparative efficiency of these two types of compound.

While the quaternary compounds show quite high values for phenol coefficient by the F.D.A. technique, the validity of this method has recently been called into serious question.^{1, 2, 3} In any event, there is room for doubt as to whether such a technique is best suited to the task of evaluating the relative sanitizing efficiency of various solutions.

Some years ago, when faced with the problem of assessing the comparative germicidal speed of various chlorine compounds, a number of different techniques, including modifications of the F.D.A. method for the determination of phenol coefficient, were tried out. In an endeavor to approximate more closely

the conditions under which a sanitizing solution has to do its work in actual practice, a glass slide method was finally developed which gave by far the most satisfactory results.⁴ This method also permitted the use of very short periods of exposure to the germicidal solution, a point of considerable importance, since in many instances under practical conditions only a few seconds' contact is allowed. Preliminary tests showed that this glass slide technique, with slight modifications, could be used equally well with quaternary compounds, hence it was selected for the comparative tests to be reported in this paper.

DESCRIPTION OF GLASS SLIDE TECHNIQUE

In the glass slide technique, a 20-24 hour growth of the test organism on an appropriate agar medium is washed off and suspended in sterile distilled water. After filtration through a No. 1 Whatman paper the suspension is standardized to match the turbidity of a suspension of *Staphylococcus aureus* giving a plate count of 200,000,000 per ml. One ml. of suspension is then introduced into 60 ml. of a 1:10 dilution of sterile skim milk in a container of such dimensions that the depth of the liquid is 1½".

A previously sterilized slide is dipped into the seeded skim milk suspension so that the lower half of the slide is immersed. It is then carefully drained

* Presented before the Laboratory Section of the American Public Health Association, at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946. Contribution No. 247 (Journal Series) from the Division of Bacteriology and Dairy Research, Science Service, Department of Agriculture, Ottawa, Canada.

against the rim of the container for approximately 10 seconds and placed upright to drain upon a pad of sterile filter paper in a specially constructed draining can. Sufficient slides to run the desired number of tests on a given dilution of a product are prepared consecutively, following which the tests are carried out before the films of diluted skim milk have dried over more than 25 per cent of the area.

Previous to preparing the slides, 100 ml. portions of the solutions to be tested have been prepared with sterile distilled water. These are placed in 100 ml. beakers and brought to the desired temperature in a water bath. The slide first prepared is then drained of any excess liquid on the filter paper, dipped into the test solutions and gently agitated for the required period, which usually runs between 1 and 20 seconds in the present studies. It is then quickly removed, dipped momentarily into a beaker of tap water to rinse off the adhering germicide and minimize bacteriostatic action, shaken sharply once to remove excess rinse water, placed in a Petri dish and the plate immediately poured with an appropriate agar medium. The remaining slides in the set are similarly treated in correct sequence. After an appropriate period of incubation, the colony count of each plate showing less than 500 colonies is made and recorded.

In the sanitizing of equipment, utensils, etc., we are usually more interested in reducing the numbers of organisms below a certain arbitrarily established limit than in complete sterilization. It was therefore decided to take as the end point approximately 99.9 per cent destruction. To arrive at this figure, control plates are prepared at regular intervals during each day's run by dipping sterile slides into a second container of diluted skim milk in which the concentration of test organisms is only 1/60 to 1/600 of that of the original

skim milk suspension. These slides are drained in the same manner as those treated with the germicide, then dipped momentarily in fresh tap water before plating. The average colony count on these control slides, multiplied by the appropriate factor, indicates the approximate number of organisms present on the regular slides before treatment. By dividing this figure by 1,000 a value is obtained representing the number of organisms remaining after 99.9 per cent have been destroyed.

ADVANTAGES OF GLASS SLIDE TECHNIQUE

Compared with the phenol coefficient technique, the most obvious advantage to the bacteriologist is the avoidance of the "skips" and "misses" which are so commonly encountered with that technique. Although irregularities are sometimes encountered, there is generally a steady drop in count with increasing period of exposure or increased concentration of germicide. Similarly, replicate runs conducted a week or more apart have generally indicated a satisfactory degree of reproducibility with this technique, as indicated by the data in Table 1. After all, it is reasonable to expect better agreement between replicate runs where 99.9 per cent destruction is taken as the end point than where the end point is taken as the killing of the last, most resistant, cell.

Another important advantage is that the glass slide technique more closely approximates the conditions under which a sanitizing agent has to work in actual practice. It measures the ability to kill organisms present on a surface in a film of organic matter, rather than freely suspended in the germicide. Furthermore, as a result of gentle agitation of the slide while immersed in the germicide, any superiority of a given product in detergent action has an opportunity to display itself and, by mechanical removal of the film and its accompanying

c—“ “ “ 62 “

bacteria, to reduce the number remaining on the slide.

Finally, attention should be drawn to the flexibility of this technique. The test organism, temperature of testing, period of exposure, concentration of germicide, plating medium, etc., may all be varied to suit the needs of the investigator.

EXPERIMENTAL

The products selected for comparative testing were representative of those on the market in Canada at that time, and included Roccal and R-2-L, both 10 per cent solutions of alkyl-dimethyl-benzyl-ammonium chloride, Hyamine 1622, di-isobutyl-phenoxy-ethoxy-ethyl-dimethyl-benzyl ammonium chloride in powder form, and Emulsept, a 10 per cent solution of N(acyl colamino formyl-methyl)pyridinium chloride. For comparison, two hypochlorites were selected. One, Dalglish Liquid Bleach, containing about 12 per cent available chlorine, is widely used throughout Eastern Canada. The other, Klenzade X4, is a newer product, said to be buffered to lower the pH and to render it more stable.

Time will not permit a detailed presentation of the results of these studies. They have included evaluation of the

comparative germicidal efficiency against each of the test organisms at 20°C., while with three of these similar comparisons have also been made at 45°C. In addition, the effect of adjusting the pH has been studied with both *Staphylococcus aureus* and *Escherichia coli*. To give a general idea of our findings, a Table 2 has been constructed showing the periods of exposure necessary to effect 99.9 per cent destruction of each of the test organisms with one of the three concentrations of germicide tested. While this presentation tends to magnify certain small differences, as compared with the tables containing the complete data, it still serves to indicate certain important differences between the two types of sanitizing agent. For example, it clearly shows that against *S. aureus*, *Micrococcus candidus* and spores of *Bacillus panis*, the hypochlorites are definitely less effective than are the quaternaries. Against the vegetative cells of *B. panis* they are approximately equivalent, while against cheese starter organisms the hypochlorites are definitely more effective. The results from tests with flat sour organisms (21 hr. cultures) indicated destruction of >99 per cent of the cells by Roccal within 5-10 seconds, and by Dalglish hypochlorite within 10-20 seconds. How-

<i>S. typhimurium</i>	200	5	5	8	8	1	5

ever, the number of spores present was so great that the 99.9 per cent end point had not been reached after 40 seconds' exposure. The sharp differences in resistance to quaternaries shown by Hucker to characterize the spore forms are not evident in the vegetative cells.

With the Gram-negative species, *E. coli* and *P. aeruginosa*, the hypochlorites are definitely superior, the advantage being greater than that in favor of the quaternaries against *S. aureus*. Incidentally, it is interesting to note that while other workers have reported *P. aeruginosa* as being much more resistant to quaternaries than is *E. coli*, our results with the glass slide technique have shown *Pseudomonas aeruginosa* to be the more easily killed. A possible explanation for this may be that the *P. aeruginosa* cultures contained a few highly resistant cells, so that, although 99.9 per cent destruction is accomplished in a relatively short time, yet the destruction of the last surviving cell may require a much stronger concentration or a longer exposure period than was necessary for *E. coli*. This point requires investigation.

Tests conducted against *S. aureus* at 45°C. indicated that there was some enhancement of germicidal activity of the quaternaries at the higher temperature, but the effect was slight compared with that noted for the hypochlorites. On the other hand, against *E. coli*, the quaternaries showed a more marked increase in activity at the higher temperature. Adjustment of the reaction to around pH 10 stimulated the activity of the quaternaries against *S. aureus* more than against *E. coli*; however, the effect was slight compared with that shown by the hypochlorites in solutions adjusted to pH 6.

Although it is not so evident from the data in Table 2. Emulsept was almost invariably less effective than were the other three quaternaries, while Klenzade X4 was similarly less effective than Dalglish.

It will be noted that the time required to destroy 99.9 per cent of the test organisms with the glass slide technique is a very small fraction of that required to effect complete sterilization with the F.D.A. technique or its modifications. Since in the glass slide technique the cells are present in a film of diluted skim milk, it seems unlikely that this difference is due entirely to a lesser amount of organic matter present than in the F.D.A. method. More probably it is due to (a) the smaller number of cells to be destroyed (varying between 8,000 and 160,000 per slide), and (b) the fact that while a very high percentage of the cells is usually destroyed within the first few seconds, an occasional cell survives for several minutes. The numbers present in the film in the glass slide technique are considerably higher than might be expected on the surfaces of washed food handling equipment and utensils,⁵ while the amount of organic matter in the film of skim milk is also much greater. It would seem reasonable, therefore, to expect equally rapid destruction in actual plant operations.

In view of the recent evidence of strong bacteriostatic action displayed by some quaternary ammonium compounds in the F.D.A. technique,^{1,2} considerable attention was given to the possibility that bacteriostasis might affect the results obtained with the glass slide technique. It was found that with the higher concentrations (used against spores of *B. panis*), quite marked inhibition of growth of *S. aureus* resulted, even where treated slides had received the customary dip in tap water to reduce the carry-over of residual germicide. With a concentration of 200 p.p.m. the zone of inhibition rarely exceeded the area of the slide; with weaker concentrations it was scarcely noticeable. This bacteriostatic effect was confined to the three Gram-positive species tested, even 1,000 p.p.m. having no effect upon the Gram-

negative species. The bacteriostatic effect was usually confined to the area above and adjacent to the treated slide, the test organisms growing freely on the remainder of the plate. While this effect was quite evident on a crowded plate, by the time the number of colonies approached the 99.9 per cent end point it was usually difficult to see much evidence of bacteriostasis. Consequently, it is believed that any error introduced by the bacteriostatic effect is slight compared with that in the F.D.A. method, and it is unlikely that such error has influenced the results to a significant degree. From a practical standpoint, this effect may be regarded as an advantage in that the residual film of a quaternary solution on a treated surface could be expected to continue its activity against any remaining organisms.

SUMMARY

To recapitulate, the glass slide appears to offer certain advantages in the evalua-

tion of the efficiency of various types of sanitizing agents. Quaternary ammonium compounds, like chlorine compounds, show differences in their relative potency. In general, the former are more effective against the Gram-positive organisms, while the hypochlorites tested show an even greater advantage against the Gram-negative species tested. While the quaternary compounds show some responses to favorable adjustments in temperature and pH, these are much slighter than those shown by the hypochlorites.

ADDENDUM

Since this paper was prepared, the following modifications have been adopted: (a) instead of receiving only a momentary dip, treated slides are agitated in tap water for 5 seconds before being plated; (b) control slides are shaken vigorously 25 times in 100

ml. sterile physiological saline solution in a 4 oz. screw-cap jar, the slide itself is plated out and 5 ml. of the saline plated separately. From these the total number of organisms originally present on the slide is calculated and this figure used in determining the end point of 99.9 per cent reduction.

Congenital Defects in a Year of Epidemic Rubella*

R. E. OBER, M.D., R. J. M. HORTON, M.D., AND
ROY F. FEEMSTER, M.D., DR.P.H., F.A.P.H.A.

*Epidemiologists and Director, Division of Communicable Diseases, Massachusetts
Department of Public Health, Boston, Mass.*

A SUPPOSEDLY benign disease suddenly assumed much more serious aspects, when Gregg¹ in 1941 first reported the relationship between rubella in the pregnant woman and congenital defects in infants. As evidence accumulated, a number of serious congenital defects appeared to be directly attributable to the occurrence of rubella in pregnancy. The Australian cases reported by Gregg and others occurred following a large outbreak in 1940 in an area where the prevalence of rubella had been low for a number of years. The accumulation of a large number of susceptible adults resulted in many pregnant women becoming afflicted simultaneously. Realizing that this same situation might be occurring in Massachusetts, but unrecognized because of its relative infrequency, a survey was planned to determine if such anomalies appeared to be resulting from rubella in this state.

SURVEY METHODS

The first step in this investigation was to send letters describing the problem to eighty well known specialists in the following fields: obstetrics, pediatrics, ophthalmology, and otolaryngology. All were asked whether they had observed in their practice specific defects in the

new-born such as had been previously described, and which could be attributed to rubella in the pregnant woman. Replies were received in the affirmative from six of these specialists enumerating a total of 10 such cases. Although only a few cases were thus discovered, it was felt that the problem warranted further study.

The second and most important phase of the study was an attempt to analyze the problem from a statistical viewpoint. The year 1943 was selected for such a study for several reasons: Nearly 35,000 cases of rubella had been reported to the department during that year, nearly twice the usual incidence; it was recent enough for individual memories to recall important facts; the children would be old enough for the anomalies to have been recognized at the time of the study.

The approximate number of females who had rubella in Massachusetts in 1943 was estimated from the list of reported cases for that year. It was found that 5,085 females in ages 15-49 inclusive had rubella in 1943. Since only 1 per cent of girls 15 and 16 are married in Massachusetts, the omission of those under 17 decreased the number to be surveyed to nearly 3,000. A complete list of the females in the age group 17-49 was compiled from the original report cards sent in daily from local boards of health.

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946

The notification of communicable diseases from the various communities in the state list the name, address, age, and sex of the individual so reported. Marital status is not usually given. Accordingly, our list of adult female cases contained no information regarding marital status. Realizing all of the difficulties which would be encountered in seeking information from these individuals, various approaches to the problem were attempted. First, four communities were selected which have large, active health departments, coöperating closely with the State Department. They were asked to investigate the cases listed for their communities. This did not prove to be a satisfactory method even in these communities because of the lack of properly trained personnel who could devote the necessary time to the problem. It would have been even less satisfactory in the smaller cities and towns in the state. A brief trial of collecting information personally by departmental employees disclosed that the method was too time-consuming. The only practicable method seemed to be to canvass the group by mail.

A small pamphlet was prepared describing in simple understandable terms the purpose of the survey and the reason for requesting the information. This pamphlet was mailed to each woman on the list, and a return postal card was enclosed which was to be filled out and returned to the department. Each postal card was marked with a code number corresponding to the name of the woman in our file, so that she could be identified without signing the card. The first question on the card asked if the woman was married at the time that she had rubella in 1943. If the answer was negative, the remaining questions were not to be answered. As might be expected, some who did not read the pamphlet and card carefully became irate and wrote sarcastic replies. Fortunately, the vast majority who replied appeared to

have understood the purpose of the card, and filled it out satisfactorily. A second card was enclosed to be given to an acquaintance who had had rubella while pregnant, if any such cases were known. This card, of course, had to be signed and returned to the department in an envelope. A follow-up letter was sent out at a later date to those women who failed to respond to the first questionnaire.

As a third step in the investigation, a letter was sent to approximately 6,000 physicians in the state, and to several institutions for the care of defective children, asking for information that they might have on rubella during pregnancy. Since rubella is not well reported, it was thought that some unreported cases of the disease during pregnancy might be found in this way and that information might be obtained in regard to women who did not reply to the questionnaire. This portion of the survey is not yet completed.

RESULTS OF THE SURVEY

Table 1 shows the response to the survey by mail of the reported cases in females. No questionnaires were sent to women who were obviously college or nursing students or inmates of institu-

tions. This eliminated 234 names from the list. Of the 2,834 women to whom the questionnaire was sent, 1,164 (41 per cent) replied. Replies from the original questionnaire totaled about 25

per cent, the remainder being elicited by the follow-up letter. The errors in reporting were mainly in age or diagnosis.

Of the 1,164 women who responded

to the questionnaire, 438 (38 per cent) were married at the time of their infection; 49 (11 per cent) of those who were married were pregnant when they had rubella. In addition, 5 cases of rubella in pregnancy which occurred in years other than 1943 were brought to our attention; 2 were sent to us by local health departments, and 3 responded to the second questionnaire card mentioned above.

The 54 cases discovered in this portion of the investigation are presented in Table 2. We are unable to account for the small number of cases which were reported in the last 2 months of pregnancy.

The congenital defects reported in cases 1, 2, 6, 8, 9, and 53 are typical of those previously reported as following maternal rubella. The defects listed for cases 27 and 42 are both commonly found in infants, and their relationship to the maternal infection might be questioned. We have included them in this table as defects for several reasons: Swan, et al.^{4,5,6} have reported several cases of defective infants following maternal infection in the second trimester of pregnancy; the same authors have reported strabismus among the defects found in their cases; several authors have mentioned the occurrence of feeding problems among their cases. No defects were found in this series fol-

lowing maternal infection in the last trimester.

In Table 3, it will be seen that, of the 5 women who had rubella during the 1st month of pregnancy, 2 aborted, 2 had defective infants, and 1 infant was normal; thus 80 per cent of the infants were either lost or defective. In the 2nd month, 2 infants were stillborn, 2 were defective, and 4 were normal, or 50 per cent were lost or defective. In the 3rd month, 2 aborted and 1 was defective, with 6 infants normal, or one-third of the infants lost or defective. In the 4th month, there were 1 abortion and 1 defective child, with 3 infants normal; an incidence of 40 per cent lost or defective. In the remainder of pregnancy there were: 1 minor defect in the sixth month; 2 stillbirths which occurred in the seventh and eighth months; 1 defective infant for which the month of pregnancy was not known. In the 54 cases, there were 8 defective infants and 9 pregnancies which terminated in abortion or stillbirth.

Only 628 replies have as yet been received to the questionnaires which were sent to physicians in the state. Of these, 39 had treated approximately 170 cases of rubella in women of child-bearing age in 1943. Thirteen of these women had been pregnant at the time of their infection. Data on 4 of these cases were incomplete; 5 of the 8 cases

in the first trimester had defective infants, in 1 case there was an abortion, and only 2 infants were normal. The single case reported in the third trimester produced a normal infant.

We were disappointed that physicians failed to remember or report more cases of rubella in the second and third trimesters of pregnancy. It does not seem plausible that rubella selects women in the first trimester of pregnancy. Undoubtedly the knowledge that important defects occur during that period focused attention on those who were most likely to show abnormalities.

DISCUSSION

Although a large number of cases of congenital defects following maternal rubella have been reported, the majority of these have been discovered by investigating pregnancies which resulted in defective infants. This may have given a distorted view of the incidence of defective offspring from pregnancies during which the mother has contracted rubella. Two recent surveys have approached the problem with the purpose of determining the proportion of defective children which might be expected from such pregnancies. These surveys of Fox and Bortin² and of Aycock and Ingalls³ included 15 cases. All of the defects observed were in instances in which the rubella had occurred during the first trimester of the pregnancy. Of the 11 cases which occurred in the first trimester, 3 showed defects, an incidence of 28 per cent, compared to 23 per cent

in the present survey. A 4th infant was stillborn, giving a total of 6 (25 per cent) lost and defective infants, compared to 50 per cent in Table 3.

In Table 4, we have combined the 54 cases from this study, 11 cases from Fox and Bortin, and 4 cases from Aycock and Ingalls. The data are given by trimester rather than by month in order to include the largest possible number of cases. The total proportion of infants lost and defective for the three periods is: 50 per cent for the first; about 14 per cent each for the second and third. It is interesting to note in comparison that the data presented on the effects of poliomyelitis in pregnancy by Aycock and Ingalls show a somewhat similar proportion of lost and defective infants, namely, 56 per cent, 26 per cent, and 14 per cent for the three periods. However, the proportion lost by abortion and stillbirth after poliomyelitis is much higher, and the number of defectives much lower. The figures given in Table 4 for the total period of pregnancy are probably not a very close approximation to the true picture due to the small number of cases in late pregnancy. Undoubtedly, the lack of reported defects in late pregnancy causes observers to overlook instances of rubella late in the period.

With the exception of Aycock and Ingalls,³ no previous authors have emphasized that abortions and stillbirths may result from infection of the pregnant woman with rubella. The frequent interruption of pregnancy by other more

serious diseases is well known. It is apparent from the data presented here that the interruption of pregnancy as a sequel to maternal infection with rubella is frequent enough to deserve further investigation. The number of abortions and stillbirths uncovered in our survey is as large as the number of defective children.

A definitive study of the effects of rubella and other diseases during pregnancy on the resulting child has yet to be done. Such studies would involve finding cases while the mother is ill with the disease, verifying the diagnosis and the stage of pregnancy, following the pregnancy to its conclusion, obtaining careful autopsies on all infants lost by abortion or stillbirth, and following up infants to the age of 12 to 15 years, if necessary, to catch all important abnormalities. This type of investigation would be of considerable value, but would take a number of years to complete. Meanwhile, it is necessary that estimates of the gross effects on the fetus of maternal disease during pregnancy be determined as rapidly as possible. As suggested by Fox and Bortin,² more surveys of this type are needed for rubella. The total of 78 cases so far reported, which have been collected on a comparable basis, give some indication of the incidence of defective infants to be expected following maternal infection with this disease. The addition of more cases from other similar surveys would greatly strengthen the inferences which can now be made. Except for poliomyelitis, no information is available as yet on the incidence of defects after other diseases, although several are known to cause such defects.

In spite of the striking incidence of abnormalities of pregnancy during the first trimester, we must be cautious in

attributing a causal relationship to rubella for all the defects found in this survey. We can be sure that some of them would have occurred if the mothers had not had rubella. Comparisons are needed with outcomes of pregnancies not complicated by communicable diseases as well as with those complicated by other virus and bacterial diseases.

SUMMARY

1. The results of a survey of adult females who had rubella in 1943 to determine the effects of the disease on infants are outlined and discussed.
2. Of 54 pregnancies discovered in replies to questionnaires sent to females 17-49 years of age, infants with abnormalities were observed in 8, abortions or stillbirths occurred in 9. Eleven of the 17 abnormal pregnancies were in women who contracted rubella during the first trimester.
3. Of 9 pregnancies reported by physicians in response to questionnaires, only 3 produced normal infants. Eight of the 9 women, however, contracted rubella in the first trimester.
4. Caution should be observed in attributing all such defects in infants to rubella.
5. The need of more comprehensive surveys to determine the comparative incidence of abnormal pregnancies in other virus and bacterial diseases as well as abnormalities in pregnancies not complicated by communicable diseases is discussed.

Public Health Aspects of Dehydrated Foods*

Food and Nutrition Section

SINCE the termination of hostilities, production of dehydrated foods has shown a decrease due primarily to cancellation of government contracts. Thus, production of dehydrated vegetables for the fiscal year 1945-1946 has been estimated at approximately 91,300,000 lbs.; this figure does not include production for army procurement. If this were included, the total would probably be about 100,000,000 lbs., compared with 196,041,000 lbs. for the fiscal year 1944-1945.

Production of dried eggs for 1943, 1944, and 1945 is given in Table 1.

TABLE 1

*Dried Egg Production in the United States**

Year	Whole lbs.	Albumen lbs.	Yolk lbs.	Total lbs.
1943	252,903,000	2,093,000	6,976,000	261,972,000
1944	311,369,000	2,310,000	7,063,000	320,742,000
1945	96,988,000	1,710,000	7,164,000	105,862,000

* Bureau of Agricultural Economics, U. S. Dept. Agr.

Dried egg production (whole, albumen, yolk) during the first 5 months of 1946 amounted to 64,528,000 lbs., compared with 77,236,000 lbs. for the first 5 months of 1945.

Although production of dehydrated foods has shown a tendency to decrease in post-war months, it is still an important segment of the food industry. The committee has therefore deemed it ad-

visable to bring together the more pertinent information published since the report¹ of the committee.

DEHYDRATED VEGETABLES

There have been no further publications on the bacteriological aspects of dehydrated vegetables since those cited in the committee's report in 1946.¹

Considerable work has been undertaken on the sulfuring of vegetables (particularly cabbage, potatoes, and carrots) to preserve their keeping qualities and vitamin C content better.^{2,3} Sulfite does, however, destroy thiamine.⁴ The Russians apparently had used the method before it was commercially applied in the United States, as evidenced by a report by Sisakyan just recently available.⁵ In this connection, the committee Chairman has received from D. I. Spiridonov his book (in Russian) on "Concentrated Foods" which not only includes the Russian technique of dehydration, but their technological methods of preparing concentrated foods.⁶

The latest data relative to the nutritive value of commercially dehydrated fruits and vegetables have been set forth by Pavcek, et al.⁷ Mallette and his co-workers¹ have also published a well planned investigation on the nutritive value of commercially dehydrated vegetables.

* Progress Report of the Committee on Foods (Except Milk).

COMMITTEE ON FOOD (EXCEPT MILK)

Organized 1932. Published reports: *Year Books* 1933-1934, 1934-1935, 1935-1936, 1936-1937, 1937-1938, 1939-1940, 1940-1941, *A.J.P.H.*, July, 1945, Mar., 1946

Mahoney, et al.⁸ have carried out experimental work on the vitamin content of canned, frozen, and dehydrated peas. The peas were laboratory processed. After 6 months' storage (temperature not given) of the dehydrated product, vitamin C levels amounted to 20 per cent of the original content; when stored under carbon dioxide, the peas had a higher level of vitamin C than when stored in air or in a vacuum. Vitamin C retention on the basis of dry weight, of the stored products, after cooking was 19 per cent as compared with the original content. The dehydrated peas retained about one-half of their original thiamine content during 6 months' storage. A recent paper by Mallette, et al.⁴ indicates that commercially dehydrated cabbage, white potatoes and sweet potatoes, when stored for a year maintained their vitamin potency, with the exception of vitamin C. Patton and Comin⁹ stored dehydrated foods in sealed and unsealed containers for 6 months at 75-80° F. They obtained no consistent effect on the loss of carotene and thiamine in peas, corn, wax beans, peaches, and plums during storage with different types of containers. Carotene was lost more rapidly than was thiamine.

DRIED EGGS

Bacteriological workers in this field have concentrated their efforts on the study of organisms of the *Salmonella* group. The public health significance of this group has already been discussed at length.¹ Winter and coworkers in a recent paper¹⁰ determined pasteurization times and temperatures necessary to destroy different *Salmonella* types in liquid whole eggs. It was found that these organisms were not difficult to destroy. *S. senftenberg* and *S. cerro* were found to be the most resistant types, and *S. pullorum* the least resistant. The resistance of *S. senftenberg* differed with the strain. These workers found that

Salmonellas of the types *S. pullorum*, *S. oranienburg*, *S. montevidео*, *S. tennessee*, *S. anatum*, *S. bareilly*, *S. typhimurium*, *S. meleagridis*, *S. london*, *S. newington*, *S. derby*, *S. rubislaw*, *S. oregon* and *S. kentucky* were destroyed in liquid whole egg at 150° F. within 0.3 minutes; at 148° F. 0.8 minutes; at 146° F. 0.8 minutes; at 144° F. 1.2 minutes; at 140° F. 2.6 minutes, and at 138° F. within 3.7 minutes. At the higher temperatures of 148° and 150° F. there would seem to be some danger of film formation in the pasteurizer. Payawal, et al.¹¹ found that the region of denaturation of liquid whole egg, as determined viscometrically, occurred within the range of 132.8° F. to 150.8° F. Above 163.4° F. whole egg coagulates almost instantaneously.

McFarlane, et al.¹² have presented data and have discussed the bacteriological methods used in the examination of egg samples, and conditions which may affect bacterial counts during handling and processing. In a later paper¹³ these workers indicate measures of sanitation necessary for the production of a clean dried egg product.

Although there are no bacteriological standards for dried egg, as pointed out by McFarlane and coworkers¹² agencies of the U. S. Department of Agriculture concerned with the production and purchasing of dried eggs are encouraging manufacturers to produce a commodity having a plate count (72 hr. incubation at 32° F., using tryptone-glucose-extract agar) under 300,000 organisms per gm.; a direct microscopic count under 15,000,000 per gm., and with *Escherichia coli* absent in 0.001 gm. A direct count of 10,000,000 per gm., or under for a high quality powder is in accord with observations of Bartram¹⁴ and of Lepper, et al.¹⁵

DEHYDRATED FISH

As pointed out in the committee's last report,¹ there is no commercial

production of dehydrated fish in the United States. Considerable work has been undertaken in Great Britain on fish dehydration. The results of the bacteriology of dehydrated fish have recently been published by Shewan,¹⁶ who found that a dehydrated product made from good quality material under reasonable hygienic conditions was not sterile but might contain up to 100,000 organisms per gm. The flora consists chiefly of micrococci, and of the cocci growing at 37° C., 0-29 per cent are coagulase-positive and hence potentially capable of producing enterotoxins. This is of considerable public health importance because the most suitable way of utilizing dehydrated fish is by incorporation with potatoes in the form of fish cakes. Since starch media are excellent for enhancing the production of staphylococcal enterotoxins, and since Shewan found that growth occurs in such fish cakes even at 15° C., it would appear that cakes made from dehydrated fish should never be kept unfried in a warm room, but should be cooked immediately.

Tarr¹⁷ has recently published results of his latest work on the microbiology of dehydrated fish. His data indicate that precooked fish, during dehydration, becomes contaminated with bacteria, molds, and yeasts. Mold development was apparent in dehydrated fish stored at 25° C. when the moisture content of the product became 16.8 to 18.3 per cent. Mold also developed, although not visible macroscopically, at moisture contents of 13.2 to 13.6 per cent. In two samples of 19 to 19.7 per cent moisture, the number of viable bacteria decreased sharply during storage, while a third sample showed a slight apparent increase. Both total volatile base and trimethylamine increased markedly in dehydrated fish stored at certain humid-

ities at which viable bacteria and molds decreased.

ADMINISTRATIVE PROBLEMS OF INDUSTRIAL MEDICINE

THE Special Review Article presented in this issue by Dr. L. J. Goldwater opens up what is perhaps the most complex and difficult problem to be found anywhere in the wide field of health and medical administrative policy; and the ultimate answer is, as yet, far to seek.

There are at least seven more or less distinct functions involved in the promotion of industrial health which may be listed as follows:

1. The provision of a healthful environment, including not only protection against specific accident and poison hazards but sanitary facilities, air conditioning, illumination, and other conditions essential for health and efficiency.
2. The education of the employed individual in the general principles of personal hygiene, particularly as adapted to the specific conditions of his employment.
3. Preemployment examination to determine the suitability of a given individual for his specific task.
4. Prompt diagnosis of new conditions requiring medical attention, whether of occupational or non-occupational origin.
5. First aid for such conditions as arise suddenly within the plant.
6. Treatment of disease, on a non-emergency basis.
7. Rehabilitation of the individual who, on account of partial disability, may require special preparation for and adjustment to, productive activity.

For the provision of these seven types of service, there are four different agencies in the picture: industry, labor, the medical profession, and the public; and any two or more of these agencies may coöperate in solving parts of the problem. The possible complexities of administrative relationship stagger the imagination.

In the past, enlightened industry has taken the lead in this field. In some large plants all seven of the functions listed are performed under the direction of management and with excellent results. In most large industries, some provision is made for the first five of these functions. Of late, organized labor has assumed an increasing role. The inclusion of health and welfare clauses in labor-management agreements is likely to become routine practice in many well-organized industries, and some of the stronger unions are already building up highly developed medical services for their members under labor auspices,

creating new vested interests which may be difficult to reconcile with a broad and all-inclusive program.

So far as the medical profession is concerned, it is difficult, as Dr. Goldwater points out, for the individual practitioner to fit into a comprehensive plan; and it is clearly impossible to visualize any such program on a fee-for-service basis. Prepayment is essential to adequate medical care for the middle economic groups of our society; and such care can only be provided with economy and efficiency on the basis of group practice. By the adoption of these two devices the medical profession can render the real service of which it is capable.

The public comes into the picture in two ways. We have pointed out that large industries have, in certain instances, come close to solving the problem by themselves. For the small industry, however, such a solution is impossible. Only through the leadership of the health department (or, in some communities, by that of a university medical center) can the small factory receive the preventive health and medical service which it so sorely needs. We look for substantial progress along this line as the health departments of our cities awake to their opportunities. The second contribution which the public will ultimately—in spite of misguided opposition—make to this picture will be through the passage of legislation for the prepayment of the costs of medical care.

Management, labor, the medical profession, and the public all have their stake in the outcome; and none of them can be left out of an ideal program. Yet, after all, the individual worker is at the center of the picture. He, or she, is a human being. He, or she, needs coördinated personalized health facilities, health education, and medical care. We must not cease to strive for a unified program directed toward an individual who is the same individual, whether within the walls of the factory or at home. Furthermore, the industrial worker is generally a member of a family; and his health care and health counseling should be correlated with that available for the other members of the family of which he forms a part.

There is a certain essential distinction between the first two and the last five of the specific functions listed above. Provision of healthful conditions within the factory walls and educational adjustment of the individual worker to those conditions are primarily problems of the industrial community itself. We may perhaps visualize as a promising avenue of approach a program in which a specialist in industrial hygiene would be primarily in charge of these functions. In a large plant he would be responsible to management—or, better, to a joint committee representing management and labor. In small plants, he might be an employee of the local health department, preferably with an advisory committee representing labor and management.

The other five functions, from preemployment examination at one end of the chain to rehabilitation at the other, involve problems primarily related to the individual worker. They could ideally be performed by a group practice unit of the medical profession acting under a prepayment plan. The preventive and curative aspects of the program should be tied together, however, by the co-operation of the specialist in industrial medicine as an associated member of the group practice unit. Where the group practice unit has sufficiently far-sighted medical administrative leadership, the group might, on its own initiative, supply to the industry its preventive as well as its curative service.

There is no single, perfect solution of this problem now in sight. There is rather a challenge to the inventiveness of management, labor, the medical profes-

sion, and the public to find empirically the best plan that will fit a given local situation. For management and labor, the need for coöperation in the meeting of a common problem is called for rather than insistence on vested interests. For the medical profession, it seems certain that the principles of group payment and group practice must be essential to any sound solution. For the public health authorities, leadership in research, formulation of reasonable standards of attainment, and assistance to small industries, where desirable, would appear to be the appropriate role.

THE PROBLEMS OF CHRONIC ILLNESS

THE development of a broad and comprehensive program for dealing with chronic illness is clearly one of the outstanding challenges to the public health worker of today; and we are printing in the present issue of the *Journal* what is probably the clearest and most authoritative brief analysis of this problem which has yet been formulated. The joint statement of recommendations on "Planning for the Chronically Ill" has been prepared by a conference committee representing the American Hospital Association, the American Medical Association, the American Public Welfare Association, and our own Association. We commend it to the serious consideration of our readers.

The first step in this program is, of course, prevention. Tuberculosis and cancer are obvious examples of diseases which can be checked before they become chronic. The report does not mention streptococcosis, but we suspect that the streptococcus and the treponema lay the groundwork for many a case of circulatory disease in later life; and that the health officer who does not conduct a special program for the control of streptococcal diseases is missing a good bet.

The second essential is provision of hospital facilities for the care of chronic diseases at the stage when intensive medical care is needed; but a type of medical care with facilities for physiotherapy, occupational therapy and the like which a general hospital very often lacks and which, on the other hand, does not require much of the equipment which makes the general hospital so costly. Recognition of the fact that chronic diseases require facilities of a special kind has, however, too often led the unthinking to propose chronic disease hospitals set up as completely independent institutions, often in remote and isolated areas. This is a most unwise course. It deprives the chronic patient of the best type of medical service and it deprives the medical staff of the general hospital of invaluable experience with this most important group of diseases. The chronic disease hospital should be a specially equipped unit; but, as the Joint Report points out, "Hospital facilities for long-term illness should be built in the very closest relation to teaching centers and general hospitals."

A third essential element in the program is the nursing home for the type of patient who does not need active and continuous medical care but who cannot—for one reason or another—be cared for in the dwelling. For this purpose, public and private nursing homes should be provided under a system of licensure and inspection which is far more intensive and constructive than that now generally in force. Too often the licensing of nursing homes is carried out by state and local health departments in a purely perfunctory fashion, as a routine response to laws which require licensure of institutions which the health officer considers as unimportant, if necessary, evils.

Finally, the Joint Report considers that "the majority of persons who are chronically ill can best be cared for in home, office, and clinic." Here, the major need is for expansion of public health nursing to approach the essential ratio of one nurse per 2,000 population and for the improvement of the quality of nursing service provided. A specialized supervisor for this type of bedside care is perhaps as important as a specialized supervisor for tuberculosis nursing.

The Report emphasizes the vital importance of treating this whole subject as a branch of medicine and public health and not as a form of poor relief. One system of medicine for the poor and another system for the rich is an intolerable anachronism. It is impossible to build up a sound institution for the care of chronic illness, or to attract patients to such an institution if any suspicion of indigence is involved. We doubt whether this difficulty can be overcome until such services are transferred from welfare auspices to those of the health department or the community hospital.

It is a most favorable omen for such planning that the four major professional organizations concerned with this field should have united in so admirable a report. We congratulate our own Subcommittee on Medical Care for its contribution to this important task.

TRAINING HEALTH WORKERS FOR LATIN AMERICA

AT a meeting of the Institute of Inter-American Affairs last winter, Dr. T. I. Gandy, Chief of the Institute's Field Party in Chile, presented a review of the progress made in training health workers for our southern Sister-Republics which was at once a record of distinguished past achievement and a challenge for the future.

Dr. Gandy points out that "Following the Conference of Foreign Ministers held in Rio de Janeiro in 1942, the republics of Central and South America and Mexico suddenly realized that one of the largest inter-American programs in public health was under way. Within a short time health centers, hospitals, sewerage and water works were being constructed from Mexico to the landlocked islands of southern Chile, and from the Atlantic to the Pacific. The mighty Amazon basin was explored and control measures were instituted for malaria, leprosy, yaws and other tropical diseases. The personnel of the Institute of Inter-American Affairs was soon to be found in every country and climate of this hemisphere in their effort to reduce diseases, increase health standards, and to bring to many people their first knowledge of the meaning of public health."

The scarcity of trained professionals in the various fields of public health was immediately realized; and, through the leadership of Dr. George C. Dunham, a Training Division was organized by the I.I.A.A. for the purpose of bringing selected candidates to various institutions of higher education in the United States. During the past four years, hundreds of professional men and women from Latin America have received training here under its auspices and, upon return to their respective countries, have been appointed to key posts in the public health field.

This training program has, of course, been on a temporary emergency basis. It will always be true that a few mature men will benefit greatly by training in a foreign country; and there should be facilities in our schools of public health

for exceptional cases of this kind. Dr. Gandy, however, points out that, for reasons of economy, to minimize language difficulties, and to adapt the educational process to local needs and social conditions, the great majority of health workers for Latin America should be trained in Latin America. Particularly is this true for the preparation of public health nurses, health educators, sanitarians, laboratory workers, and various types of auxiliary personnel.

Dr. Gandy believes that such local training facilities should be developed within the framework of existing national public health services, and that these services should subsidize both the schools themselves and the students, where necessary. These students, he suggests, should be selected, at first, primarily from the ranks of those already employed in the official health departments.

An excellent example of what may be accomplished along such lines is offered by the advances made in Chile. Here, the National Health Service, the Rockefeller Foundation, and the Chilean affiliate of the I.I.A.A. have developed a comprehensive training program parallel with its advances in administrative health work. With the counsel and leadership of Dr. Hernan Romero, head of the School of Public Health, and with many instructors who have received special postgraduate training in the United States, 42 medical health officers have been graduated from the course designed for them; while sanitary and food inspectors, laboratory workers, statisticians, and health educators have fulfilled courses leading to certificates in their special fields. All in all, 244 students have received instruction in the school, while 123 public health nurses and 42 nursing aides have completed special training, courses offered in two health centers devoted specifically to that purpose.

In Puerto Rico, there is a more modest, but most promising, development of field training facilities.

We trust that more extensive provisions of this kind may be made in the various large centers of Mexico and Central and South America. It is only through local study and training centers, under national auspices and using the national language, that the health knowledge accumulated in English-speaking countries can be translated—not merely into the language of Latin America, but into the social life and the traditions of Latin America.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

The Development of Modern Medicine—By R. H. Shryock. New York: Knopf, 1947. 457 pp. Price \$5.00.

The well known medical historian author has given us a packed volume of condensed medical and cultural record of the past 350 years, abundantly documented and presented in scholarly language by a master bookmaker and printer.

It will not be thought unfriendly or snobbish to suggest that there is little of any new matter not already familiar to well educated physicians or to students and practitioners of contemporary society and its origins.

The "attempt to portray certain major aspects of medical development against the background of intellectual and social history in general" varies in its success among the twenty chapters. Rare judgment and wide familiarity with original sources are evident in a text which condenses the medical story of 1600 to 1800 in the first six chapters. These give fairly routine basic matter selected for the present special purpose. The next four chapters on Science in the Romantic Age, Medicine and the Basic Sciences, Medicine. Mathematics and the Social Sciences, and Emergence of Modern Medicine, are excellent in spirit, outlook, and suggestiveness. Familiar matter of less value is presented in Chapters XI–XV although the thread of thoughtful analysis and social interpretation is well maintained. The last five chapters are perhaps less satisfying because they deal with matters of such recent origin and implications that they savor more of contemporary journalism than of history, and yet all the facts are reliable and important, though less capable of final evaluation than those of earlier half centuries.

It is rare indeed to find an error of name and yet on one page the discoverer of cocaine is spelled once with an *o* and five lines below with an *a* (Koller and Kaller). The author seems to play casually with two spellings for the same word *virulency* and *virulence* without apparently intending any distinction or preference.

Those who study, teach, write, or think in the medical-social field will turn often and eagerly to this almost pocket manual of medical history in the making.

Physicians will welcome so correct and balanced a presentation. The educated laity will be better patients and fairer judges of their physicians if they indulge themselves in this good book.

HAVEN EMERSON

Fleas of Western North America—By Clarence Andressen Hubbard. Ames, Iowa: The Iowa State College Press, 1947. 533 pp. Price \$6.00.

A book which has attracted the attention of *Time Magazine* deserves consideration and review, and glance by the non-professional leaves no doubt that Clarence A. Hubbard has made an important contribution in bringing the systematics of western fleas from the dusty shelves of the specialized library to the workbench of the student of external parasites. The epidemiologist or experimenter with vectors conveying diverse human and animal infections will find here in convenient form a summary of the scattered literature on most of the *Siphonaptera* thus far found in the West. Identification keys have been devised for groups of fleas that previously had none. The data on the biology, morphology, types of hosts, seasonal distribution and abundance will prove very valuable, although the

entomologist may not always be willing to accept the classifications. However, anyone even superficially familiar with the subject will appreciate the tremendous amount of effort which Dr. Hubbard singlehandedly has expended, under a great deal of hardship and personal sacrifice, in making the field collections and laboratory preparations.

The description of the species are clear and well illustrated by a wealth of 'original camera lucida' drawings, which are, however, crowded together so closely that it is often difficult to determine the relationship of a specific name with its respective sketch (see pages 237, 241, 261, 276, 285 and 357). A more detailed account of the internal morphology of fleas and methods of culturing in the laboratory would have been of value. The host index to western fleas and the rapid checking index, which covers over 127 pages, facilitate use of the book. Since the subject is not static, it is not expected that the book will remain complete, but in its present form it is not up-to-date with respect to references. For example, the new subspecies, *Carteretta carteri clavata*, reported by Good in 1942 from Nevada, is not mentioned. Besides making the list of known fleas incomplete, such an omission also weakens the data on geographical distribution. Many more omissions will be found by the specialist.

It is rather unfortunate that the author attempted a presentation of data on the medical importance of fleas. His familiarity with the literature concerning this aspect is, at best, so sketchy that even as a "commentary" it must be considered inadequate. For example, the demonstration of *P. pestis* in *Echidnophaga gallinacea* in 1941 is not mentioned, and the role of fleas in sylvatic plague has been completely overlooked. Furthermore, the impression is given that fleas transmit *Bact. tularensis*, although transmission experiments by

the American entomologists, Prince and Burroughs, have repeatedly failed. Most disconcerting are the recommendations for the medieval use of salt, naphthalene, kerosene, or engine oil in the control of fleas (page 27). Recent experiences with the remarkably effective DDT have apparently made no impression on the author.

K. F. MEYER

Social Security—Selected List of References on Unemployment, Old Age and Survivors', and Health Insurance, Bibliographical Series No. 78—By Matthew A. Kelly and Hazel C. Benjamin. Princeton: Princeton University Press, 1947. 62 pp. Price, \$.75.

The Department of Economics and Social Institutions of Princeton University has done a real service in preparing this bibliography of references on the various aspects of social security.

In the discussion of the three types of social security insurance: unemployment, old age, and health, the subject is divided into general problems and philosophy, United States experience, and legislation and experience in foreign countries. This is valuable reference material for those interested in any aspect of the social security problem.

MARTHA LUGINBUHL

The Co-Operative Process Among National Social Agencies—By Ray Johns, Foreword by Shelby M. Harrison, General Director, Russell Sage Foundation. New York: Associated Press, 1946. 290 pp. Price, \$3.00.

Whether you, as a public health worker, believe in a little coöperation, a lot of it, or none at all, you owe it to yourself to read with care this treatise on the coöperative process.

It is based on the recent war experiences in coöperation and on current opinion. The author's background, as former Associate Director of USO, leaves him with few illusions as to the problems involved in getting agencies,

their board members, executives, and staffs to work together for a common goal that transcends their individual interests.

Program content is omitted. The book wisely limits itself to the keen analysis of a "process." What is presented about national social agencies applies, therefore, with equal force to national health agencies and to local agencies as well. You will be impressed with the logical, well ordered approach and the objectivity of this study and report. The style is quite unemotional. One cannot escape the feeling that he is reading an account of a difficult exploratory surgical operation—from incision, through probing and dissection, to final closure and prognosis. As a consequence, it is definitely not for the "hammock" reader; but to all persons who are devotedly and unselfishly seeking to improve the health of all people and all communities through our public health agencies, this book is "must" reading.

JOHN W. FERREE

Public Agency-Council Relationships—A Study published by the Health and Welfare Planning Department. New York: Community Chests and Councils, 1946. 47 pp. Price, \$.75.

The Department, through its Secretary, Violet M. Sieder, presents the results of a study of the relationships of public welfare organizations to councils of social agencies in 113 communities of various sizes located in different parts of the United States.

The value of publicly supported health and welfare organizations, as well as private ones participating on an absolutely equal basis in privately supported welfare councils, is demonstrated.

The advantages to both the tax supported organizations and to public officials as well as to the privately supported organizations in the community, are evident. The author criticises the

limited efforts made to maintain complete coöperation between public and private agencies in welfare councils. The volume stimulates a desire for closer and more effective coöperation between councils and public officials.

Seven questions which public welfare agencies and councils could well ask themselves are outlined in the appendix.

Sub-headings I, II, III, etc., might well have been more prominent.

HOWARD W. GREEN

Public Health Nursing Functions In The School Health Program—Prepared by the Minnesota State Department of Health and the State Department of Education, December, 1946.

Public Health Nursing Functions in the School Health Program is a compilation of material with dates of sections ranging from August, 1943, to December, 1946. Section titles are "Relationships to Health Councils," "Delineating Responsibilities between Nurse and Teacher," "Evaluation of School Health Service Program," and "Appendix."

Two state departments are given credit for preparing the material but participating individuals or divisions are not identified. The affiliation of the secretary and executive officer who signed the foreword is not revealed.

Lack of consecutive page numbering throughout, and the treatment of the same subjects in more than one section without adequate cross-references are disturbing features. An immature nurse probably would be confused by the arrangement.

An interpretation of how the school administrator functions in directing the school health program is lacking.

Good suggestions for promoting school health education are offered in the various sections, particularly in the appendix. Unfortunately, the casual organization of the material fails to give the anticipated clear-cut picture of how

school nursing may become an integral phase of school health program. For contrast, the reader is referred to sections on school nursing in the *Minnesota Manual for Public Health Nurses*.

LULA P. DILWORTH

Laboratory Control of Water Purification—By Charles R. Cox. New York: Case-Sheppard-Mann, 1946. 386 pp. Price, \$4.00.

This volume is designed for the assistance of technical personnel in water works laboratories. It is true that untrained laboratory workers are frequently employed, many of whom become proficient in water analysis but who lack fundamental chemical and bacteriological training. The author has attempted to supply this and has done an excellent piece of work. The book should be useful as well to the trained worker who frequently desires to know more of the chemical reactions involved in the various analytical procedures than is given in *Standard Methods for the Examination of Water and Sewage*.

In general the procedures given are those in use in most water laboratories but there are some additions, presumably, from the author's laboratory.

The volume would be more useful if more original references were cited. Probably these were intentionally omitted. *Standard Methods* is mentioned a few times, Whipple's *Microscopy of Drinking Water* once, one *Journal* reference is supplied, and the Public Health Service standards are referred to. A few phrases are confusing—such as "pathological diseases," and the description of the food supply of bacteria—but most of the book is clear and as concise as is consistent with its purpose.

JOHN F. NORTON

National Health Insurance in Great Britain 1911-1946—By R. W. Harris. Washington, D. C.: Public Af-

fairs Press, 1946. 224 pp. Price, \$3.25.

The author of this volume has been intimately associated with the British health insurance system, in one capacity or another, since the Health Insurance Bill was presented to Parliament in 1911. At one time an assistant secretary in the Ministry of Health, he is now Chairman of the Medical Service Subcommittee of the London Insurance Committee.

A great deal of important information is contained in this review of British experience. The early history of the Friendly Societies is presented, together with a detailed description of the types of societies and their subsequent development under National Health Insurance. The very high costs of cash sickness benefit administration by approved societies are contrasted with the low costs for administering medical benefits through the insurance committees. Interesting data are presented on patient-doctor relationships, including several case histories illustrating the types of problems dealt with.

Although the volume suffers from poor organization, it represents a valuable contribution to the literature on health insurance and an excellent source for factual data.

MILTON TERRIS

Tuberculosis As It Comes and Goes—By Edward W. Hayes, M.D. (2nd ed.). Springfield, Ill: Thomas, 1947. 220 pp. Price \$3.75.

This is a small book of 200 pages written in non-technical language especially for tuberculosis patients and their families. However, it contains valuable factual and inspirational material for tuberculosis workers, including physicians. The author, being a man of wide experience in the treatment of tuberculosis, stresses individualization.

Dr. Hayes answers many of the questions which the average patient and his

relatives wish to ask the doctor. It is noted, however, that he does not mention streptomycin or BCG.

The book can be commended for its conciseness, fairness, and common sense attitude. Apt quotations sprinkled through the pages enhance the readability of the text. There are numerous sketches illustrating various types and stages of the disease before and after treatment. These probably are more intelligible to the layman than reproductions of x-ray films would be.

Especially noteworthy are 2 chapters at the end by Laurence de Rycke, Ph.D., on "Suggestions to Patients," and "Suggestions to Visitors." These chapters alone are worth the price of the book.

JOHN H. KORNS

Veterinary Bacteriology—By I. A. Merchant, D.V.M., Ph.D., C.P.H. (3rd ed.) Ames, Iowa: Iowa State College Press, 1946. 633 pp. 137 illus. Price \$7.00.

"Some textbooks of bacteriology include sections which have been omitted purposely from this one. A section on pathogenic protozoa has not been included because such micro-organisms are logically studied in courses of animal parasitology in Colleges of Veterinary Medicine. . . . Laboratory methods of milk and water analysis are completely described in manuals of standard methods published by the American Public Health Association. Inclusion of such methods in this text would be superfluous."

Such, quoted from the preface to this third edition is self-explanatory. Whether such omissions can be used as a basis for any adverse criticism pertaining to the book can be entirely a personal opinion.

The author's decision to use "alexin" fixation instead of "complement" fixation is explained in the chapter "Cytolysis and Alexin Fixation" (Page 196); "The term complement fixation origi-

nated with Ehrlich. He believed that the complement was united to the antigen by the amboceptor, thereby he differed considerably with Bordet who thought the union was due to the action of amboceptor, or sensitizer, upon the antigen. In light of present day knowledge the explanation of Bordet is more acceptable."

Here, again, personal opinion can be the basis of critical comment. Certainly the term "alexin-fixation" does not appear in current literature such as *Venereal Disease Information* (Federal Security Agency, U.S.P.H.S.). The term "alexin" appears *only as a footnote* in a standard reference book pertaining to serology.

The Index of the book contains omissions and some errors among which are:

1. There is no mention of Aschoff or the reticulo-endothelial system, although a brief mention appears in one paragraph on page 209 of the text.
2. There are confusing index mistakes such as "Breed, R. S. 287" which should have been page 288; "Mangold 261" is found at the top of page 260.
3. The index does not mention agglutinin absorption; the text does mention it, briefly, in a paragraph on page 185.

However, the errors are slight; while the omissions can be satisfied by reference to other textbooks.

The type is good, the printing good, the illustrations good; the text sustains interest.

R. V. STONE

The Principles and Practice of Medicine (Osler)—By Henry A. Christian, M.D. (16th ed.) New York: Appleton-Century, 1947. 1539 pp. Price, \$10.00.

Osler's Principles and Practice of Medicine as revised and edited by Christian under the above title has been a standard text now for 55 years. An excellent chapter by Carr has been added tracing developments in the history of medicine as reflected in these

16 editions since 1892. The present edition has been extensively rewritten so that more than 900 of the 1400 pages have been entirely reset. Public health workers will find the text succinct, inclusive, and up to date. It is inevitable that in such a condensed treatise as this there should be conclusions that will be challenged by public health physicians as, for example, the mass prophylaxis of scarlet fever by sulfa drugs. It could also be said that the description of modified takes from cowpox vaccine is not clearly presented, and there is lacking a desirable link in the descriptions of communicable diseases with the officially adopted and international report on this subject. Nevertheless it seems doubtful whether for public health libraries a better single volume can be found in the English language.

REGINALD M. ATWATER

Methods of Vitamin Assay—*By The Association of Vitamin Chemists Inc., Chicago. New York: Interscience Publishers, Inc., 1947. 189 pp. Price, \$3.50.*

This text, consisting of nine chapters, has resulted from free discussion and exchange of ideas of the members of the Association, who edited this volume. The methods described are the result of the pooling and interchange of information on analytical techniques, thus representing the combined knowledge and experience of many persons. The background assumed is that of a laboratory technician with limited training in quantitative analysis. The scope of the book is limited to methods that have been successfully applied to a variety of foods. Revisions are planned by the Association from time to time, whenever conditions so indicate.

Chapter 1 gives consideration to the question of sampling for vitamin analyses. Chapters 2 to 7 considers in the greatest detail the best suited method

for the assay of vitamin A, carotene, thiamine, riboflavin, niacin, and ascorbic acid. In Chapter 8, selected reference to other vitamin methods are listed. Finally, Chapter 9 discusses the use of check samples in control of vitamin methods.

With this excellent start, analysts may look forward to future editions of the Association of Vitamin Chemists with interest.

HENRY T. SCOTT

Milk and Food Sanitation Practice—*By H. S. Adams, B.Sc. New York: The Commonwealth Fund, 1947. 311 pp. Price, \$3.25.*

A well written and practical source of general information on milk and restaurant sanitation for health officials. It appears to have been written for and accomplishes the purposes of giving administrators basic information in these branches of environmental sanitation for which there has been need. The views expressed are fairly representative of modern practice. The eleven appendices contain much additional material in the form of references, information about field equipment and tests, and an outline of a course for the instruction of food handlers.

WALTER D. TIEDEMAN

Tuberculosis Hospital Planning and Construction —*By J. Bruno Basil, A.L.A., Architect (rev. ed.). New York: National Tuberculosis Association, 1946. 81 pp. Price, \$1.00.*

The subject matter is treated in the manual or handbook style: the statements are readily understood; the reading of it is a pleasure and definitely invites a deeper investigation. All the major and many of the minor problems of tuberculosis hospital planning and construction are broadly presented, and various methods of solution are outlined. This pamphlet reflects wide research and objective analysis of a large amount of data. It is the best of its

type that the reviewer has ever seen and is earnestly recommended not only for those who are planning new build-

ing but also for those who are considering any extensive remodeling of existing facilities. N. STANLEY LINCOLN

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Even Its Name Is Unsatisfactory—They Say—Perhaps it is enough for you to know that a British Rheumatic Fever Committee has surveyed the current status of the prevention and management of that disease and reports findings which—so far as I can see—are not greatly at variance with the pronouncements of the experts on this side of the water. The report is full of sound common sense such as this: nothing is so likely to restore a rheumatic child's morale, as a return to reasonable exertion. A suggestion is made that the disease might better be called "heart fever."

ANON. Rheumatic Fever. M. Officer. 77, 22:217 (May 31), 1947.

Citizens of Tomorrow—Although deaths among 5-14 year olds have dropped from 3.9 (per 1,000) in 1900 to 0.9 today, there is still plenty of room for improvement. Accidents (preventable) are the chief cause of death, with rheumatic fever, communicable diseases, and appendicitis poor seconds. Teeth conditions are shockingly bad.

ANON. Health Problems of School-Age Children. Stat. Bull. (Met. Life Ins.) 28, 5:3 (May), 1947.

Justified by Its Fruits—Boosted here is the "comics" book as a health educational device. From a happy experience with "Little Willie" the writer concludes that this dubious medium really produces results in action by those who won't read but will look at "the pitchers."

BILLINGS, T. E. Venereal Disease Education. J. Ven. Dis. Inform. 28, 8:162 (Aug.), 1947.

Shaping Nutrition Policies—Four

useful papers on nutrition in public health administration begin with a world view by Boudreau, then follow a survey of new activities by Wilkins, a description of a State Department program by Getting, and further suggestions about administration by Goodhart. These names should convince you that the series is your meat.

BOUDREAU, F. G., *et al.* Nutrition in War and Peace (and three related papers). Milbank Quart. 25, 3:231 (July), 1947.

"That We Do the Job Right"—We have been trying to sneak sex education into people by disguising it with fancy names, says this writer. It's like flavoring cod liver oil with wintergreen: it may do the patient as much good but it doesn't taste any better.

GOFFIN, L. C. What Is Sex Education? J. School Health. 17, 6:151 (June), 1947.

Belsen — Coldly matter-of-fact, this account of the Army's delousing of the still-breathing remainder of the inmates—and the resulting prompt cessation of a typhus epidemic—manages to become an eloquent reminder that this hideous word will long remain the one perfect symbol of human bestiality.

DAVIS, W. A. Typhus at Belsen. Am. J. Hyg. 46, 1:66 (July), 1947.

Not Original But Good—Booster-dosing is still new enough to warrant calling your attention to an occasional review article, I assume. This is a useful one for you. Combined antigens, asserts the writer, not only do not interfere with each other but frequently they enhance the total effect.

GREENBERG, M. Use of the Booster Dose for Reimmunization. Pub. Health Nurs. 39, 8:382 (Aug.), 1947.

Out of U. S. A. by Denmark— Even though you are well versed in the essential elements of tuberculosis control programs you will be repaid for reading this eloquent and convincing plea for a world-wide attack on the disease.

HILLEBOE, H. E., and HOLM, J. International Control of Tuberculosis. Pub. Health Rep. 62. 31:1114 (Aug. 1), 1947.

Problem Drinkers Are Sick People— Man is the problem, not the bottle, the researchers in the field of alcoholism now assert. You'll be pleased with this broadminded account of plans for treatment, research, and legislation to meet our national "Lost Weekend."

HIRSH, J. Alcoholism: What Is It? Survey Midmonthly. 33. 6:163 (June), 1947.

Which Rodenticide Do You Use?—Though this paper is about the use of "1080" against rats on ships, it ends with the reminder that the poison is highly toxic for larger animals (including the alleged *sapiens* variety). The poison is a white powder which could be mistaken for flour or baking powder and probably will be. What to do if the mistake is made is set forth, but the moral seems to be: you'd better use ANTU.

HUGHES, J. H. Studies in Deratization of Surface Vessels by Means of 1080 (Sodium Fluoroacetate). Pub. Health Rep. 62, 26:933 (June 27), 1947.

Psychiatry Now Has Help To Offer— That there is any relationship between public health practice and mental hygiene is a relatively new concept and one not yet universally accepted. This is the opening premise of this paper. This introduction ought to be enough to enable you to decide whether or not you should know what the professor said about the subject to the International Health Organization.

LEMKAU, P. V. Mental Hygiene in Public

Health. Pub. Health Rep. 62, 32:1151 (Aug. 8), 1947.

More About Infant Pincushions— A prophylactic timetable is proposed calling for jabs at 6, 7, 8, and 10 months, 1 year, 15 and 18 months, then at 2, 4, and 6 years. Thereafter tetanus toxoid every 2 years. Long before the "thereafter" is reached, friendship of the child and the doctor will be firmly established—on a strictly fighting basis.

MILLER, J. J. Immunization Procedures in Pediatrics. J.A.M.A. 134, 13:1064 (July 26), 1947.

On the Altar of Modern Efficiency— During the last five years, 84 California hospitals have had outbreaks of diarrhea of the new-born, some hospitals repeatedly. And this is not a uniquely dark record! The epidemiology of the disease, its clinical aspects, and correctional procedures are set forth. If there is a single, top-priority public health emergency, this would seem to me to be it.

MOORE, J. A., *et al.* Diarrhea of the New-born. California's Health. 4, 24:189 (June 30), 1947.

Work and School— Seems incredible, doesn't it, that the (British) Health and Morals of Apprentices Act of 1802 could have permitted the employment of children for 12 hours a day. And another encouraged the factory employment of those who had reached the advanced age of nine. School and working conditions are better today for English children though there is still room for improvement—if these two papers are to be credited. They call forcibly to mind some of the related notes and beams in our own sociological eyes.

NEWT, A. A. E. and LLOYD DAVIES, T. A. The Change from School to Industry. Pub. Health. 60, 9:177 (June), 1947.

Based in Reason and on Present Knowledge— On the assumption

that poliomyelitis virus is present more frequently and for a longer time in the intestinal tracts than in the throats of both cases and carriers, nine control measures are advocated—not with the idea that they will stop an epidemic but that because of them some persons may escape infection who might otherwise become paralyzed. Don't miss this!

SABIN, A. B. The Epidemiology of Poliomyelitis. J.A.M.A. 134, 9:749 (June 28), 1947.

World Food Needs—When you contemplate the rapidly increasing numbers of newly opened hungry mouths in India and China that will be turned toward us to be fed after we've taken care of starving Europe, do you sometimes wonder how it can be done? Well, here is one of those world-wide surveys to tell us that all the hungry could be fed if . . . Did you know that only 7-10 per cent of the land area is cultivated? Did you know—you'd better read the questions as well as the answers yourself.

SALTER, R. M. World Soil and Fertilizer Resources in Relation to Food Needs. Science 105, 2734, 533 (May 23), 1947.

How To Tell Who's Undernourished—First of a series to inform health workers about the methods and the findings of nutrition demonstration units, this one gets off to an interesting start. You had better get in at the beginning.

SANDSTEAD, H. R. and ANDERSON, R. K. Nutrition Studies. Pub. Health Rep. 62, 30, 1073 (July 25), 1947.

This Will Slay You!—Average caries indices of a large sampling of post-war Italians in four cities were two to seven times lower than in the good-old U. S. A. The people examined were for the most part malnourished and the level of their oral hygiene was what you'd expect. It wasn't fluorine,

either—or low carbohydrate intake. Suggested as two possible factors are shortage of refined sugar and vitamin B deficiencies.

SCHOOR, I. and MASSLER, M. Dental Caries Experience in Post-war Italy. J. Am. Dent. A. 35, 1:1 (July 1), 1947.

Promiscuous Mis-Use Deplored—This is medicine pure and simple, but the findings should be part of your public health "info" kit. Penicillin aerosol therapy is of definite value in the management of appropriate (but only appropriate) respiratory diseases. It should not be used against the common cold.

SEGAL, M. S., *et al.* Penicillin Inhalation Therapy in Respiratory Infections. J.A.M.A. 134, 9:762 (June 28), 1947.

Shoemaker's Children—Perhaps the most disturbing part of this grim but gripping discussion (which I advise you not to miss) is the list of famous stomach surgeons—and a roentgenologist who contributed a useful diagnostic sign—all of whom developed gastric cancers which had become inoperable before they could be recognized. Forty thousand out of the 150,000 annual cancer deaths are gastric. Indifference and inertia are more to be feared than cancer phobia, concludes the writer, as he urges us to get back of the preventive, educational program.

WAGENSTEEN, O. H. The Problem of Gastric Cancer. J.A.M.A. 134, 14:1161 (Aug. 2), 1947.

Maternal Rubella—This quotation, from *King Lear* may come in handy some day, so I pass it along to you: "That foul fiend, Flibbertigibbet . . . gives the web and pin (cataract), squints the eye, and makes the harelip." The modern-day name for Flibbertigibbet is rubella, when it attacks in the first trimester of pregnancy.

WESSELHOEFT, C. Rubella (German Measles). New England. J. Med. 236, 25:943 (June 19), 1947.

years, metropolitan department of health; four years, school nurse and educational director; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Young dentist; D.D.S., M.S. degrees; recently received Master's degree in Public health; considerable research work on problem of dental caries; for further information please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Health educator; several years' experience in teaching the sciences before taking graduate training in health education; M.S.P.H., middle western university; eight years, director of health education, tuberculosis association; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

NOTE ON THE HEALTH CONGRESS OF THE ROYAL SANITARY INSTITUTE

TORQUAY, DEVON, ENGLAND; JUNE, 2-6, 1947

The Royal Sanitary Institute resumed in 1946 its series of annual Congresses, which had been interrupted by the war. The 1947 Congress, however, was the first since the war to which international delegations have been invited. A record number of 2,383 persons attended, of which 81 were overseas delegates* from 37 countries.

The Royal Sanitary Institute may be regarded as a British cousin of the American Public Health Association, although differing considerably in its history and type of membership. The Institute was founded in 1876, four years after the American Public Health Association, and it now has an enrollment of slightly more than 7,000. From the first it was an organization of sanitarians in the broadest sense, rather than primarily a medical organization. Statistics are not available, but it is believed that less than one-fourth of the present membership is made up of physicians. There are a relatively large percentage of civil, architectural, and sanitary engineers, and a substantial number of sanitary inspectors. The number of women members, especially in the public health nursing field, is relatively small.

Like the American Public Health Association, the Royal Sanitary Institute

publishes a *Journal* (bi-monthly),† holds an annual Congress, and generally promotes interest in health activities. Local sectional meetings are also held at intervals. A function not paralleled by any organization in the United States is the holding of qualifying examinations for various types of health service workers. At present some fourteen different examinations are held, covering various aspects of the fields of health visiting (public health nursing), nursery nursing, and sanitary inspection. Although certificates granted by the Royal Sanitary Institute on the basis of these examinations do not have the official legal status of our state board examinations in medicine or nursing, they are in fact requirements for employment by health departments under regulations issued by the Ministry of Health. The Institute thus plays an important part in setting standards for health visitors and sanitary inspectors in the United Kingdom and to a considerable extent in the Dominions and Colonies.

The 1947 Congress was held in Torquay, Devon, on the south coast of England. Despite the general housing shortage in England, Torquay's hotels were able to accommodate the delegates without difficulty, perhaps because early June is well in advance of the peak vacation season. The town is built on steep hills rising sharply from a sheltered bay, and with the lush vegetation of this nearly frost-free corner of England, is a most scenic spot. The Mayor and his

* The United States Government delegation included Dr. Martha M. Eliot, U. S. Children's Bureau (Chairman); Dr. Harry S. Mustard, Director of the Columbia University School of Public Health; Captain Arthur W. Loy, M.C., U.S.N., Assistant Naval Attaché at the London Embassy, and the writer (Vice-chairman). Dr. Mustard and Dr. Eliot also officially represented the American Public Health Association as President and President-elect, respectively.

† The Proceedings of the Congress will appear in the July and September issues (Vol. 68, Nos. 4 and 5) of the *Journal of the Royal Sanitary Institute*.

staff provided the utmost coöperation in making the Congress successful, and officially entertained the delegates at a reception and a garden party. As was customary of pre-war meetings, a special luncheon was given in honor of the overseas delegates.

In contrast to meetings of similar organizations as usually arranged in the United States, the Congress was run along lines which gave much time for individual discussions between members and leisure for recreational activities. Sessions were scheduled in the mornings only, from 10 a.m. to 1 p.m.; three or four sessions were held each morning concurrently. The typical session consisted of a 20 minute address by the president of the section, followed by two papers of 30 to 40 minutes each. Several short speeches, proposing votes of thanks or introducing speakers, were interspersed, leaving about one hour during which the floor was thrown open for discussion.

The Congress was divided into seven sections: Preventive Medicine, Engineering and Architecture, Maternal and Child Health, Veterinary Hygiene, Food and Nutrition, Housing and Town Planning, and Tropical Hygiene. The sessions on Preventive Medicine and Maternal and Child Health included papers on "The Scope of Public Health after 1948," "The National Health Service and the Public Health Service," and "The Present Position and Prospects in Whooping Cough Immunization," several papers on various aspects of infant mortality including one on care of premature infants, and a group of papers on public health and industrial nursing.

Environmental sanitation was discussed in papers on "Milk: A Food for Thought," "Meat Transportation," and "The Work of a Sanitary Inspector at a Busy Fishing Port," and was touched upon in papers of the Veterinary Hygiene Section such as "The Import-

tance of Cowshed Hygiene in the Transmission of Milk-borne Diseases," and of the Food and Nutrition Section in two papers on "The Microbiological Aspects of Food Quality."

The Tropical Hygiene Section heard a paper on *Anopheles* eradication in Cyprus, and an account of social welfare problems in tropical Africa.

The Engineering and Architectural groups discussed chiefly problems relating to slum clearance and development of planned housing "estates" (projects). These matters appear to be given more attention by public health workers in England than is commonly true in the United States; it is significant that the national agency dealing with housing is the Ministry of Health. A paper on "The Design and Location of Health Centres" was of especial interest to those concerned with development of these centres for the National Health Service.

Pervading the discussions of public health was the consciousness of the recently passed National Health Service Act of 1946, and its anticipated effects on the administration of public health, medical, and hospital services after the "appointed day" when the Act is to become operative, probably July 5, 1948. Not a word was said against the objectives and basic principles of the Act, which is to provide free and comprehensive public health, hospital, specialist, and general practitioner services to the entire population of England and Wales. Concern seemed to center around two general matters; first, the tripartite administration of the Service, and second, the danger of its administration being too far removed from the local level. Under the Act, preventive services will be administered by counties and county boroughs (roughly the equivalent of counties and large cities in the United States), general practitioner services will be administered by Executive Councils, each Council (with

rare exceptions) covering a county or county borough area, while hospital and specialist services will be the responsibility of Regional Hospital Boards. There will be approximately 140 administrative units in the first two groups, and 14 Regional Boards. It is evident that complex problems will arise in securing a properly integrated service. The Act provides devices for cross-representation at the various administrative levels, and the Medical Officer of Health could be a key person in coördinating the various health functions at the local level.

With respect to remote administration, there appears to be adequate provision in the Act for decentralization, but whether in fact a bureaucratic or a locally sensitive administration will be developed, will depend largely on the degree of responsibility delegated to the local bodies.

One of the most impressive aspects of the Congress was the large number of lay members of Local Authority Councils sent as delegates to the Congress. Many of the larger Authorities sent as delegates one or two members of their Public Health Committee as well as their medical officer of health and sanitary inspector. Some authorities sent only the chairman of the Public Health Committee; others only the medical officer of health. A high degree

of interest in, and in many cases knowledge of, health needs and practices was shown by some of these delegates. Councillors and aldermen taking part in the discussions added a flavor which tends to be lacking from professional meetings in the United States.

A useful feature of the Congress was printing the major papers and distributing them in advance to all the delegates. This gave the delegates opportunity to study the papers prior to delivery and to present well prepared comments in the discussion periods.

The small number of sessions, leaving afternoons and evenings free, gave adequate time for the informal meetings and personal contacts which are perhaps the most important phase of such a congress. On the other hand, there were sufficient formal conferences to permit a substantial number of delegates to express their views during the discussion periods.

Particular note should be made of the hospitality extended to the overseas delegates by officials of the Royal Sanitary Institute and the city of Torquay. Everything was done to make our attendance at the Congress professionally profitable and socially enjoyable.

BURNET M. DAVIS, M.D., SURGEON,
USPHS

Division of Public Health Methods

INSERVICE TRAINING COURSE IN THE
COLLECTION AND DISPOSAL OF
GARBAGE AND REFUSE

The School of Public Health, University of Michigan, Ann Arbor, Mich., announces a two day Inservice Training Course in the Collection and Disposal of Garbage and Refuse to be held at the School of Public Health Building, University of Michigan, Ann Arbor, Mich., on October 27 and 28.

The course is designed especially for the benefit of public works officials.

However, others who are interested are invited to enroll and attend the course. The enrollment fee is \$5, which should be paid at the time of registration. Enrollment will be closed on October 20. Applications should be submitted to the School of Public Health, University of Michigan.

The course will consist of presentation of various aspects of garbage and refuse disposal by individuals expert in the various subjects, followed by group discussions. The subjects to be discussed

will include the responsibility for control, methods of collection, and equipment for collection, and various specific methods of disposal.

NATIONAL BUREAU OF STANDARDS
ESTABLISHES DIVISION OF
COMMODITY STANDARDS

Dr. E. U. Condon, Director of the National Bureau of Standards, recently announced the consolidation of the Divisions of Commercial Standards and Simplified Practices to form the new Division of Commodity Standards.

The bureau has been serving actively as a coördinator in the development of voluntary simplified practices—elimination of uneconomical variety in manufactured products—and in the preparation of commercial standards as typified by the work of the American Standards Association and the American Society for Testing Materials. The Division of Simplified Practices will continue both of these activities and in addition will carry on the Federal Specifications work, vital in the preparation of specifications for government purchases. Edwin W. Ely, formerly chief of the Simplified Practice Division, has been appointed chief of the new division.

VENTILATION OF GARAGES AND PLANTS

Adequate ventilation of plants, warehouses, and garages, to eliminate carbon monoxide and other dangerous gases from gasoline-powered engines can be assured if enough air is in circulation in such places, according to a recent report of the Bureau of Mines. The publication is based upon one of a series of investigations of the occurrence and effects of toxic gases in the minerals industry. Investigations conducted for several years by the Health and Safety Branch of the Bureau of Mines has disclosed the fact that many gasoline-powered engines used in coal mines and tunnels are unsafe because of the dangerous gases generated and the hazard con-

nected with the fuel. The same conditions may exist in garages. To determine the amount of air necessary for proper ventilation the investigators considered three factors: rate of fuel consumption, volume of exhaust gas, and the concentration of carbon monoxide in the gas.

Copies of the publication, *Ventilation Involved in the Use of Gasoline-Powered Equipment in Enclosed Spaces (Not in Mines or Tunnels)*, may be obtained free from the Bureau of Mines, Dept. of the Interior, Washington 25, D. C.

BUREAU OF DENTISTRY IN NEW YORK
CITY HEALTH DEPARTMENT

A Bureau of Dentistry was recently created within the New York City Department of Health. Heretofore dental services have been provided through a division of the Bureau of Child Hygiene.

The director of the new division is Harry Strusser, D.D.S., who has been in charge of the dental division since 1929. Henry C. Sandler, D.D.S., is assistant director. The new bureau employs a total of 150 dentists and 141 dental hygienists.

DR. CAMERON HEADS AMERICAN
CANCER SOCIETY

Charles S. Cameron, M.D., was appointed Acting Medical and Scientific Director of the American Cancer Society at the meeting of its Board of Directors in June. The appointment follows the resignation of A. W. Oughterson, M.D., Medical and Scientific Director and Vice President, who has served in this capacity since April, 1946.

Dr. Cameron came to the society in June, 1946, as Assistant Medical and Scientific Director. In January, 1947, he also assumed the duties of director of the Service Department.

SPECIALIST SERVICE TO OUTLYING
TERRITORIES

On July 19, a group of five top staff

men from Cook County Hospital in Chicago took off from Minneapolis for Alaska. They were the first group in a project set up by the American Medical Association to take specialized service to the territories and Western Indian Reservations.

The specialists will carry with them facilities for a portable hospital and will spend a month in the territory.

In September, groups will visit Indian reservations in the West, and in December, 10 or 12 physicians will be sent to Puerto Rico and the Virgin Islands for similar services.

This is planned as a continuing project and more teams will be sent out next year.

"TRUSTEE" BEGINS PUBLICATION

The American Hospital Association announces the publication of a pocket size magazine for hospital governing boards to be called "Trustee." Editorially, it will be "educational, readable, and strictly pertinent to the realm of trustee responsibilities."

It is the result of the work of a special committee made up of Ray E. Brown, Superintendent of University of Chicago Clinics, Chairman; Graham L. Davis, Director, Hospital Division, W. K. Kellogg Foundation; R. O. D. Hopkins, Executive Director, United Hospital Fund of New York; and William B. Seltzer, Director, Mt. Sinai Hospital, Cleveland.

The price will be \$2.00 per year for member trustees and administrators and \$3.00 per year for other persons. The American Hospital Association, 18 East Division Street, Chicago 10, Ill.

FELLOWSHIPS FOR WOMEN

The American Association of University Women, 1634 I Street N.W., Washington 6, D. C., announces a group of fellowships for graduate study or research for the academic year 1948-1949. These fellowships are awarded in gen-

eral to candidates who have completed two years of residency on work for a doctorate degree or have already received such a degree. The greatest importance is attached to the project on which the candidate wishes to work.

There are two types of Fellowships:

1. The National Fellowships are open to American women for study in the United States and offer \$1,500, with one fellowship of \$2,000.

2. The International Fellowships are open to members of the International Federation of University Women for study in the United States or abroad. One fellowship will be awarded to a Latin American woman for study in the United States. The awards in the international group of fellowships range from \$300 to \$1,500.

For detailed information address the Secretary, Committee on Fellowship Awards. Closing date for applications is December 15.

PREVENTION OF DERMATITIS

The July, 1947, issue of *Industrial Hygiene Newsletter* carries two items of interest on the subject of dermatitis. The first, "Poison Ivy—Hazard of Vacation and Vacation," gives a brief report on the present status of preventive measures to protect against possible contact with the plant. It also makes some suggestions with regard to treatment. The final paragraph should be of interest to many—"Injudicious treatment of poison ivy is often worse than no treatment at all. It must therefore be emphasized that any severe case of poison ivy dermatitis should be cared for by a physician."

The second item is one of a series of discussions. This is part II entitled, "Occupational Dermatitis and Methods of Prevention—Cleanliness." Louis Schwartz, M.D., and Paul C. Campbell, Jr., M.D., the authors, explain the importance of cleanliness including the body and clothing in prevention of occupational dermatitis. They go further to

outline precautions that should be taken by certain persons for whom the usual cleaning agents might not be suitable.

The *Industrial Hygiene Newsletter* is published by the U. S. Public Health Service, Washington, D. C.

NEW YORK STATE CEREBRAL PALSY COMMISSION REPORTS

The year-old New York State Legislative Cerebral Palsy Commission recently made a preliminary report to the state legislature. It found that the State Department of Health carries over 4,600 such cases on its registers, that another thousand are under the care of the Department of Mental Hygiene, and that approximately one-third of all children in special classes in public schools are victims of cerebral palsy.

At present, although there is no known cure for those who have normal mentality (65 to 75 per cent of all), "there is perhaps no other group for whom rehabilitation to even a slight degree makes so much difference and is so important." The Commission has reached the following conclusions:

1. State care of cerebral palsy victims is inadequate and insufficient although its responsibility for this group is the same as for other disabled groups.
2. Specialized diagnostic and treatment centers should be available at an early age for every child afflicted.
3. Educational, medical, and therapeutic services should be expanded and integrated.
4. Inpatient care should be provided for those in need of such care.
5. At least one model center for diagnosis, treatment, and research should be established as soon as possible.
6. Specialized training for physicians, nurses, and teachers for this field should be stimulated.
7. The present formulae for state and federal assistance for the care of such cases should be restudied.

The first model center to be established will probably be at LeRoy, N. Y., on a fifty acre estate offered to the University of Rochester for that

purpose by Mr. and Mrs. Ernest L. Woodward. Operational costs for treatment services would be supplied by the state, and research and training would be conducted by the university's medical school, Strong Memorial Hospital staff, the National Foundation for Infantile Paralysis, and other groups.

ATOMIC RADIATIONS UNIT FORMED

Dr. J. G. Townsend, Chief of the Industrial Hygiene Division, U. S. Public Health Service, recently announced the formation of an Atomic Radiations Unit in the Chemical Section of the Division. Mr. Duncan Holaday, Engineer (R), is in charge of the new Unit.

In making announcement of this new activity, Dr. Townsend expressed the belief that many institutions and industries have been handicapped in their use of radioactive isotopes and high energy machines because of their lack of information about the safe handling of dangerous quantities of radioactive materials. The new Atomic Radiations Unit, working through industrial units in the states, will help institutions and industries evaluate their hazards and establish safe working conditions.

LANSING-INGHAM COUNTY HEALTH UNIT

The City of Lansing and the County of Ingham in Michigan became a consolidated county health unit on July 1. Its director is Roelof Lanting, M.D., who previously served as Lansing City Health Officer. The combined population (1940) of the city and county is about 130,000.

DR. KESSLER HEADS NATIONAL COUNCIL ON REHABILITATION

The election of Henry H. Kessler, M.D., as President of the National Council on Rehabilitation (1705 Broadway, New York 19) was recently announced.

Dr. Kessler is Chairman of the Council on Industrial Health of the American

Medical Association, and Consultant in Orthopedics and Prosthesis Services to the Federal Office of Vocational Rehabilitation, and a member of the New Jersey State Rehabilitation Commission. His "cineplastic amputation" technique is unique in the field of surgery. He spoke before the British Council on Rehabilitation in London on July 25.

FEDERAL GRANTS FOR MENTAL HEALTH RESEARCH

The first federal grants for research in mental health under the new National Mental Health Act—25 grants to institutions or individuals in 9 states—were recently announced by Thomas Parran, M.D., Surgeon General of the U. S. Public Health Service.

This program was authorized by the U. S. Congress in 1946 and received an appropriation of 7½ million dollars on July 8, 1947. In addition to the mental health activities of the Public Health Service, this will finance a threefold program of research on mental illness, development of local mental health facilities, and training of mental health personnel.

"EYE-BANK" SET UP IN NEW ORLEANS

An affiliated "Eye-Bank" has been organized in New Orleans, La., which will have the coöperation of the Louisiana State University Medical School and the Tulane University Medical School and Hospital, it was announced recently at national headquarters of The Eye-Bank for Sight Restoration, Inc., 210 East 64th Street, New York. Other affiliated Eye-Banks are functioning in Boston and Chicago.

PHARMACY SECTION IN HOSPITAL DIVISION, U.S.P.H.S.

A newly created pharmacy section has been established in the Hospital Division of the U. S. Public Health Service for the further development of the pharmaceutical activities in the Marine

Hospitals and their adjunct medical relief stations. This action brings an organized pharmacy service for the first time to the oldest of the hospital groups operated by the federal government.

The new pharmacy service in the Hospital Division will be under the direction of George F. Archambault, graduate and former faculty member of the Massachusetts College of Pharmacy.

DR. SAYERS LOANED TO UNITED MINE WORKERS

R. R. Sayers, M.D., Medical Director, U. S. Public Health Service, and Director of the U. S. Bureau of Mines since 1940, has been granted leave without pay to accept the chairmanship of the medical board recently established by the Trustees of the Welfare and Retirement Fund of the United Mine Workers of America. In this position, Dr. Sayers will advise trustees of the miners' fund on health and medical problems. He will also assist state and local public health authorities, as well as coal operators and unions, in carrying out recommendations contained in the Medical Survey of the Bituminous Coal Industry issued last spring by Rear Admiral Joel T. Boone.

Assignment of Dr. Sayers to this position is in line with the Public Health Service policy of making expert personnel available to official and voluntary non-profit organizations to assist in the developmental stages of new and significant health undertakings.

CHILDREN'S BUREAU GRANT AT HARVARD SCHOOL OF PUBLIC HEALTH

To provide for expansion of the educational program and the facilities for training in the field of maternal and child health and related branches of public health, the Harvard School of Public Health has received a grant of Children's Bureau funds from the Massachusetts Department of Public Health. To the basic disciplines will be added

further training in nursing, social service, and especially the administrative aspects of child health. Further field training facilities will also be developed.

JOURNAL OF THE INTER-AMERICAN ASSOCIATION OF SANITARY ENGINEERS

Volume I, No. 1 of the *Journal of the Inter-American Association of Sanitary Engineers* was published in July, 1947. As the name indicates, this is the official *Journal* of the recently organized Inter-American Association of Sanitary Engineers (see *A.J.P.H.* of July, 1947, p. 955, for an announcement of its formation).

The lead article in the first issue of the new *Journal* is "The Sanitary Engineer Looks Forward," by Abel Wolman, Dr. Eng., previously published in professional magazines of the United States, including the *American Journal of Public Health*, November, 1946. The *Journal* uses both the English and Spanish versions of all original articles; for articles already published elsewhere, only the language is used in which the article has not appeared.

NEW ARMY MEDICAL CENTER

What is planned to be the greatest medical research center in the world will be built at Forest Glen, Md., by the Corps of Engineers for the Office of the Surgeon General, AUS, according to a recent announcement made by Major General Raymond W. Bliss, the Surgeon General. In keeping with technological advances in all fields, the center will be equipped to anticipate and meet the medical problems of the future as well as to cope with those of the present.

Designated as the "Army Medical Research and Graduate Training Center," the project will consist of a 1,000 bed general hospital capable of expansion to 1,500 beds; the Army Institute of Pathology building; the Army

Medical Museum and Center Administration building; Central Laboratory Group buildings; and the Army Institute of Medicine and Surgery. A working library, animal farm, staff quarters, and other buildings are included in the plans.

PERSONALS

Central States

FRANK F. BOWMAN, M.D.,† on May 1 retired as Health Officer of the city of Madison, Wisc., a position he has held for 19 years. He was honored at a farewell dinner given by present and former employees of the city health department.

LEWIS DODSON,* formerly Director of Public Health Practices for the National Sanitation Foundation at the University of Michigan School of Public Health, Ann Arbor, became Director of Environmental Sanitation of the City-County Health Department, Denver, Colo., effective September 1.

SOPHIE FLEVOLD, R.N.,† was appointed on August 1 as Director of the Public Health Nursing Association of Des Moines, Ia. She was previously assistant Director of the Dayton, Ohio, Visiting Nurse Association for 9 years.

MARION I. MURPHY,† has been appointed Associate Professor of Public Health Nursing, University of Michigan, Ann Arbor, Mich., as of August 1. Miss Murphy was formerly Assistant Director of the Bureau of Public Health Nursing, Michigan Department of Health.

A. NEUWIRTH, M.D.,† is at present stationed in Germany as the Medical Director for Germany for the American Joint Distribution Committee. Dr. Neuwirth was formerly Health

* Fellow, A.P.H.A.
† Member, A.P.H.A.

Officer, Iron-Ontonagon Health District, Mich.

J. BURRIS PERRIN, M.D.,† became Deputy Health Commissioner and Director of the Division of Maternal and Child Health of the Peoria, Ill. Health Department on July 1. He was most recently in the Medical Corps, AUS, and Director of the Division of Maternal and Child Health and Crippled Children in the Colorado Department of Health.

A. LLOYD TAYLOR, M.D., has accepted a position as Research Supervisor in the Wyandotte Chemicals Corporation Research Laboratories, Wyandotte, Mich., where his experience will be applied in the field of industrial detergents. Dr. Taylor has had many years experience in this field both as Director of Research for Oakite Products and as Director of the Department of Chemistry for Pease Laboratories, New York.

Eastern States

ANNA M. BANUS, nutritionist in the Berkshire district office of the Massachusetts Department of Public Health, has resigned to accept a position as assistant professor in the Department of Home Economics of Western Reserve University, Cleveland, Ohio.

FRANK E. COUGHLIN, M.D.,† has been named County Commissioner of Health of Rensselaer County, N. Y.

WILLIAM P. FORREST, M.D., has been appointed assistant director of the WHO Interim Commission Headquarters Office in New York City. He was chief medical officer with the United Nations Relief and Rehabilitation Administration's mission to the Ukrainian Soviet Socialist Republic.

SUE T. GOULD, M.D.,* Columbia County, N. Y., Commissioner of Health has resigned that post, effective October 1.

GRANVILLE W. LATIMORE, M.D., M.P.H.,* Director of the Education Department, American Cancer Society, New York, N. Y., has resigned to accept appointment as Director of the Bureau of Health Education, New York State Department of Health, Albany, N. Y.

MADELEINE LAY, has been appointed Education Secretary of the American Association of Psychiatric Social Workers, New York, N. Y., to act as an adviser to schools of social work and to social work departments of universities in setting up standard curricula for the training of psychiatric social workers. This work has been made possible by a grant from the Commonwealth Fund for 2 or more years.

JAMES E. PERKINS, M.D.,* was appointed Deputy Commissioner of Health of New York State. Associated with the New York State Department of Health since 1934, Dr. Perkins has served successively as Epidemiologist, District State Health Officer, and as Director of the Division of Communicable Diseases. On January 1, 1946, he was appointed Deputy Commissioner by former Commissioner EDWARD S. GODFREY, JR., M.D.,* recently retired.

DAVID D. RUTSTEIN, M.D.,* has been appointed Professor of Preventive Medicine at Harvard Medical School, Boston, Mass., succeeding JOHN E. GORDON, M.D.,* who since July 1, 1946, has been head of the department of epidemiology in the School of Public Health. Since 1946, Dr. Rutstein has been Medical Director of the American Heart Association and the American Council on Rheumatic Fever and a consultant to the Joint Research and Development Board of the Departments of War and Navy.

CHARLES D. SHIELDS, M.D.,† has resigned the position of Commissioner of Health of the City of Buffalo,

N. Y., to accept a commission as major in the U. S. Army Medical Corps. EDWARD B. BUKOWSKI, M.D.,† who has been Buffalo's deputy health commissioner, has been appointed acting commissioner.

Southern States

J. C. CANADA, M.D., was named Director of the Pontotoc County Health Department, Ada, Okla., effective July 3.

FREDERICK A. JOHANSON, M.D., has been named Director of the U. S. Marine Hospital (National Leprosarium) at Carville, La., by the U. S. Public Health Service. He has been with the institute for over 20 years. Dr. Johanson succeeds G. A. FAGET, M.D.,† former director, who died recently.

VICE ADMIRAL ROSS T. MCINTIRE, wartime Surgeon General of the U. S. Navy, and formerly White House physician, has been named director of the new National Blood Program of the American Red Cross. Dr. McIntire will have supervision of the most far-reaching health program in the peacetime history of the Red Cross being undertaken in direct response to the urgent need of the medical profession for blood in saving of life as well as in treatment and prevention of disease.

MASON ROMANE, M.D.,* became Director of the Division of Cancer Control of the Virginia State Health Department July 1, after serving as full-time public health officer in Petersburg, Va., since 1941.

WILLIAM B. ROSSMAN, M.D., has been appointed Director of the Bureau of Mental Health of the West Virginia State Department of Health. Plans for the new bureau were completed by the Public Health Council at a meeting in Charleston June 30.

MARY JANE SCOTT, Senior Nutritionist with the Arkansas State Health De-

partment since 1942, has resigned to become a Professor of Home Economics Education at the University of Arkansas.

GEORGE L. WINN, M.D.,† resigned as Director of the Comanche County Health Department, Lawton, Okla. effective June 30.

Western States

PHILIP A. BEARG, M.D.,* has resigned as Health Officer of San Luis Obispo County, California.

MAURICE BRODSKY, M.D., of the U. S. Public Health Service, was recently appointed assistant chief of the Hawaiian Tuberculosis Bureau. He replaces WILLIAM MURLIN, M.D., who joined the staff of Leahi Hospital, Hawaii.

LLOYD FLORIO, M.D., Dr.P.H.,* Professor of Public Health and Preventive Medicine at the University of Colorado Medical Center has been loaned to the city of Denver for a 6 month period to reorganize the City and County Health Department on the basis of a comprehensive survey recently completed by EDWARD G. MCGAVRAN, M.D.,* new dean of the University of North Carolina School of Public Health.

CHANGES IN HEALTH PERSONNEL IN STATE OF OREGON:

F. HERBERT COLWELL, M.D.,† has been reappointed to the post of Director of the Vital Statistics Section of the State Board of Health. Dr. Colwell held the position until early this year, but resigned to accept an offer in Washington State.

LAURA P. WELLS,† has resigned as Nutrition Consultant for the Maternal and Child Health Section to supervise the school lunch program of the State Department of Education.

* Fellow, A.P.H.A.
† Member, A.P.H.A.

JAMES V. HAWKINS,[†] is the new Sanitarian in Klamath County, replacing LLOYD SEALEY, who resigned in May. Mr. Hawkins has served with the U. S. Public Health Service in Kansas City and as a sanitarian in Alaska, Washington State, and Texas.

WILLIARD J. CLOYES has resigned as Sanitarian of Lane County, a position he held since 1940 to become city manager of Springfield, Ore.

G. D. CARLYLE THOMPSON, M.D.,[†] was appointed Director of the Division of Preventive Medical Services for the State Board of Health, August 1. Dr. Thompson also became State Epidemiologist. He was the first Maternal and Child Health Director of the State Board of Health, having served in that capacity from 1937 to 1940 and during the war was attached to the Surgeon General's Office in Washington, D. C.

EDWARD A. REINKE,* has been appointed Chief, Bureau of Sanitary Engineering, California State Health Department, effective July 1. Mr. Reinke's appointment follows 27 years of service in the Bureau of Sanitary Engineering.

F. E. WIGGINS, M.D., has replaced FRANK M. GARDNER, M.D., as the Health Officer of the City of San Bernardino, Calif.

Foreign

C. K. CHU, M.D.,* has been named assistant director of Field Services for China, WHO Interim Commission. Dr. Chu received his M.D. degree from the Peking Union Medical College and a degree of Doctor of Public Health from Yale Medical School. He has been granted one year's leave from his post as director

of the Chinese National Institute of Health to work with WHO.

DOMINGO F. RAMOS, M.D.,* of Havana, Cuba, left New York on July 30 for a tour of Latin American countries in connection with the emergency feeding program for children in war devastated countries. Dr. Ramos, who serves on the faculty of the Medical College at the University of Havana, was formerly Minister of Health of Cuba.

Death

GUY HENRY FAGET, M.D.,[†] for 25 years a distinguished officer of the U. S. Public Health Service, and noted for his pioneer work in treating leprosy with sulfa drugs, died July 17 in the U. S. Marine Hospital, New Orleans, La.

The Place of Nutrition in a Public Health Program*

WILSON JAMESON, K.C.B., M.D., F.A.P.H.A. (Hon.)

Chief Medical Officer, Ministries of Health and Education, London, England

THE study of nutrition has extended over a longer period than the 75 years covered by these meetings of the American Public Health Association, and both our countries have made material contributions to the advancement of this branch of knowledge. Though much fundamental research still remains to be done, we now know enough to enable us to say how various population groups should be fed if health is to be maintained and, indeed, made more robust. This is of the first importance, for good nutrition easily heads the list of objectives in a public health program.

The recent world war made it necessary for Britain to prepare a plan for national nutrition—no easy task for a country that, with its present density of population, cannot possibly be self-supporting. It was decided that the Ministry of Health should be responsible for advising the Government on nutritional policy from a scientific point of view and that the Ministry of Agriculture should endeavor to produce food,

and the newly created Ministry of Food to import and distribute food, in accordance with such advice. We had an interdepartmental committee of officers that worked quietly behind the scenes and insured that no conflicting advice would be offered to the Ministers concerned.

The requirements of the various sections of the population were defined in terms of nutrients and the amounts of different foods necessary to supply these nutrients were estimated. Production and import programs were planned accordingly. Thus the newer knowledge of nutrition was applied for the first time, on a nation-wide scale, to the feeding of the people in Britain.

Practically everyone in Britain was employed on war work of one kind or another, and wages were reasonably high. The manufacture of all goods except those strictly necessary was prohibited, so people had little else than food on which to spend their earnings—and often not too much of that. The position is much the same today.

The main steps taken by Government were as follows:

1. *Subsidies*—It was essential for us

* Presented before the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 7, 1947.

to produce as much food at home as we could, therefore subsidies of all sorts were given to farmers.

Again, food had to be sold at prices comparable with those existing before the war; otherwise wage increases would have got out of hand. Accordingly much of the food purchased by Government at fairly high prices abroad was sold to the public below cost.

In 1946-1947 some £345 million were spent by the Government on these subsidies. Had they been removed, the cost-of-living index, which in the middle of that year stood some 31 per cent above the September, 1939, figure, would have been about 55 per cent above. The food index alone would have increased from 22 per cent to about 60 per cent above that of the immediate pre-war period.

2. *Rationing*—Rationing began in January, 1940. It was based on the principle that all essential foods, even if in short supply, should be equally available to everyone to an extent necessary to maintain health, and at controlled prices. The foods so dealt with were meat, bacon, cooking fat, butter and margarine, cheese, tea, sugar, and preserves.

At the end of 1941, what was known as the "points" scheme was introduced. Every person was entitled to a certain number of points monthly in exchange for which he could purchase a number of articles of food in short supply such as canned meat, fish, fruit and vegetables, and certain cereals. This scheme added palatability and variety to an otherwise rather drab diet and was made possible largely by the generous help of the people of North America.

In 1942 a "personal points" scheme gave everyone a small personal allocation of candies—I along with most other fathers benefited but little from this gesture.

Other foods such as milk and eggs were not rationed but were controlled

to this extent, that the public could purchase only the amounts advertised from time to time. Milk frequently fell as low as two pints per person per week. Bread was never rationed during the war—though it is now.

3. *Communal feeding*—In the latter part of 1940 local authorities were encouraged to establish what were called "British Restaurants" at which substantial meals could be obtained at cost price without the surrender of any coupons. Similar canteen arrangements were extended to factories and these were subsequently made compulsory in factories where more than 250 persons were employed. This arrangement was criticised by some who thought that no food should be provided in a communal eating place without the surrender of coupons. It was never intended, however, that the basic industrial ration should meet the needs of those who were working often at hard and unaccustomed tasks away from home. A good mid-day meal at such establishments went far to relieve the household supply, and was eaten mainly by those who really needed the additional food. At the same time an extra ration of cheese was made available for workers for whom canteen facilities were not available, such as those working on the land or in coal mines. There are still more than 800 of these "Civic Restaurants," as they are now called, in operation by local authorities and more than 12,000 factory canteens.

4. *Priority classes*—These were pregnant women, nursing mothers, and children up to school-leaving age. The schemes devised for these groups were known as the Welfare Foods Service and the School Milk and Meals Service. Invalids were also given special privileges and their requirements were attended to by a Special Diets Advisory Committee of the Medical Research Council. All these schemes are still in being.

The Welfare Foods Service is concerned with mothers and with children under 5 years of age. As soon as a woman knows she is pregnant she draws a ration book for her unborn child, on presentation of a certificate from a doctor, a midwife, or a public health nurse. She is then entitled to 7 pints of milk a week at less than one-third the market price, or free if she cannot afford to pay. She may also obtain free cod liver oil or vitamin A and D tablets and, for a small payment, a supply of concentrated orange juice. Additional eggs and meat are also allowed her. After the baby is born the mother and child between them may get as much as 14 pints of milk a week, together with vitamin supplements, until the child is a year old. After that the allowance is 7 pints of milk a week for the child till he is five years old and, of course, the normal vitamin supplements. Up to the age of 2 years the child may have national dried milk if it is preferred, as well as an extra allocation of eggs.

So far as milk is concerned the scheme has been about 100 per cent successful, but the "take up" of the orange juice, the cod liver oil, and the vitamin tablets has not been so satisfactory.

When the child reaches school age, i.e., 5 years, he loses the welfare foods but is entitled to the School Milk and Meals Service. He gets $\frac{1}{3}$ pint of milk in school in the middle of the morning and another $\frac{1}{3}$ pint in the afternoon if he wants it. Unfortunately the afternoon milk has had to be discontinued temporarily on account of shortage of supplies. In addition, between the ages of 5 and 18, he is entitled to $\frac{1}{2}$ pint of milk at home every day at the full price. All school milk is now free—over 92 per cent of children in public and private schools are having it.

The school children's milk amounts to about 50 million gallons a year. If this is added to the welfare milk, the

total is 230 million gallons of free or cheap milk for mothers and children, representing about 40 per cent of all supplies.

School dinners in special school canteens are being rapidly extended. At present just over 50 per cent of children attending State-aided schools benefit, but it is intended as soon as may be to provide dinners free for all school children—just now a charge is made for the cost of the food only, roughly about 5d. a meal. Every effort has been made to provide dinners of the highest possible nutritional standard. Extra meat, fat, sugar, and skimmed milk powder have been allowed and the calorie value of the meal for the older children is about 1,000, for the younger 750.

A scheme of family allowances has been introduced in Britain; for each child except the first the parents receive a cash allowance of 5/- a week. There was a considerable demand for a bigger cash allowance but, rather than agree to this, Government decided to give additional benefits in kind by maintaining permanently the Welfare Foods Scheme and the School Milk and Meals Scheme.

5. *Fortification of food*—Margarine had vitamins A and D added to it in January, 1940, to bring its value up to that of summer butter. Later on the amount of vitamin D was increased. This vitamin was also added to national dried milk in 1945 as a safeguard against rickets. Flour has not been fortified. Instead, we have had a national loaf made of 80 to 85 per cent extraction flour, with some calcium added to neutralize the effects of phytic acid, which apparently interferes with the absorption of calcium and iron.

6. An educational campaign on a large scale was undertaken by Government—through the press, the radio, on the movies, and by local health demonstrations—to tell the public about the foodstuffs available and to encourage

use them. This was an essential element in the Government program and was generally much appreciated.

EFFECTS OF THE WARTIME FOOD POLICY

1. *Consumption of food*—Before the war the consumption of the more expensive and nutritionally more valuable foods rose with income. The poorest families were generally those with large numbers of children and among them the consumption of those valuable foods was lowest. The war altered this. Full employment with good wages and food subsidies, together with controlled prices, made it possible for even the poorest families to secure a good diet.

Here are some comparisons of 1945 with the period 1934–1938:

Milk consumption	rose	by	30	per	cent
Potatoes	"	"	58	"	"
Bread	"	"	21	"	"
Vegetables	"	"	22	"	"
Sugar	fell	"	33	"	"
Meat	"	"	23	"	"
Fats	"	"	20	"	"

2. *Health*—The war seemed to offer a wonderful opportunity to establish the value of various methods of assessing the nutritional state of samples of the population. We had generous help from the Rockefeller Foundation in this connection, and numbers of elaborate surveys based largely on laboratory technique were undertaken. I wonder how much we have learned from all these. For my part I think the clinical assessments carried out by my good friend and your well known expert, Dr. Sydenstricker, were of more practical value than many of the complicated studies made in Britain and on the continent of Europe.

Anyhow, for what they are worth, here are some of the results of such surveys and assessments as we could make with the means at our disposal:

a. Clinical examination revealed malnourishment in less than 1 per cent of a large sample of the population.

b. A survey carried out by the Medi-

cal Research Council of 16,000 people of all ages and occupations showed, from hemoglobin estimations, a decline in the incidence of anemia in women and children.

c. In 1940–1941 the growth rate, i.e., the height and weight increases, of children aged 4–14, was lower than before the war. By 1943, however, the rate was better than pre-war, and this improvement has been maintained up to 1946.

d. *Dental caries*—I think it is generally accepted that the incidence of dental caries is considerably influenced by diet. I have no figures for the country as a whole but here are the results of careful dental inspection of school children in Cambridge and in London. In Cambridge, in 1938, the percentage of temporary teeth found to be carious was 21.5 and only minor changes were recorded in 1939, 1940, and 1941. In 1942, however, the figure was 14.3, in 1943 it was 13.9, and in 1944 it had fallen to 10.8.

In London, Lady Mellanby made careful surveys of the dental condition of comparable groups of 5 year old children in 1929, 1943, and 1945. She found that between 1929 and 1943 a great improvement had taken place both in the structure of the deciduous teeth and in their resistance to decay. In 1943, 22 per cent of the children were "caries free" as compared with about 5 per cent in 1929. In 1945 she found the individual teeth significantly better in structure and with less caries than in 1943 while the percentage of carious teeth showing arrest of the disease was almost twice as large in 1945 as in 1943. She attributes the improvement to the increased calcifying properties of the diet particularly of pregnant women, infants, and young children. She has just told me that the improvement was still maintained in 1946.

e. *Vital statistics*—The work of Stuart, Burke, and their colleagues in Boston, and of Ebbs, Tisdall, and others

in Toronto, and of the People's League of Health in England, showed that the health of mothers and of infants and the incidence of complications in pregnancy and childbirth are influenced for good by improvement in the mother's diet. We did what we could, as I have told you, to apply these findings on a nation-wide basis. We did what we could, also, to secure as good conditions as possible for women during the antenatal and lying-in periods, though our good intentions were apt at times to be disturbed by bombs and rockets. Here are the relevant figures for England and Wales for 1945 as compared with those for 1938:

1. Maternal mortality (excluding abortions) declined by 46 per cent—excluding infection the decline was 38 per cent.

2. The stillbirth rate declined by 28 per cent.

3. The infant mortality rate declined by 13 per cent.

4. The neonatal mortality rate declined by 13 per cent.

In 1946 the fall continued in all these rates and each of the new figures was the lowest ever recorded. I have no doubt whatever that these results are due in the main to the priorities in essential foodstuffs granted to the mothers and children of Britain under a wise system of wartime rationing.

The fate of adolescents, heavy manual

workers, housewives, and single persons living without canteen facilities was not so good. It is not too good now for the non-priority classes after more than two years of so-called peace. Nutrition is not merely a matter of calories and vitamins. There are associated indefinable psychological elements as well. It is hardly surprising that a presumably victorious nation whose whole resources were expended on the war effort should experience some degree of psychosomatic disorder when, at this late stage, its bread has had to be rationed and whose belt has had to be tightened yet another notch or two. All this will pass, of course, and better days will come. We have at least this to be thankful for—and here I quote the words of Lord Woolton, a great Minister of Food—spoken in 1942: "I think we shall be able to say when the war is over that as a result of the application of scientific knowledge to food we have enabled the next generation, which has to build a new age and which indeed has a formidable task before it, to approach the work with healthy bodies. I believe we shall go through this war with no malnutrition amongst the children of the nation. That is one of the things for which we are working and praying, and I hope we shall succeed."

For my part, I hope I have shown you that we have succeeded.

An Outbreak of Smallpox in New York City*

ISRAEL WEINSTEIN, M.D., F.A.P.H.A.

Commissioner of Health, City of New York, N. Y.

THE OUTBREAK

ON February 24, 1947, Eugene Le Bar, a '47 year old merchant who had lived in Mexico for six years, started a bus trip from Mexico City to New York City. Ordinarily, such an occurrence would not merit any particular attention, but in this case, it initiated a chain of events that led to headlines in papers throughout the country, hourly bulletins on the radio, laboratories working on a 24 hour schedule to produce vaccine, and hundreds of thousands of people standing on line for hours in order to enter a health center, hospital clinic, or police precinct. The arrival of a sick man in New York City caused millions of people to be vaccinated.

Le Bar was apparently well when he entered the bus, but that evening he be-

came ill. The symptoms were rather mild, consisting of little more than headache and pain in the back of his neck. Two days later he developed a rash. In order to relieve the headache, he took large amounts of a proprietary headache powder as well as aspirin. He arrived in New York City on March 1 and registered at a midtown hotel. Although he was not feeling well, he did a little sightseeing and also walked through one of the large department stores.

On March 5, he entered Bellevue Hospital where he remained until March 8. Because of the rash, he was transferred to Willard Parker Hospital, the communicable disease hospital in Manhattan. There, four diagnoses were considered—drug eruption, erythema multiforme, Kaposi's varicelliform eruption, and smallpox. Smallpox was rejected as the diagnosis because there was denial of exposure to the disease, a well developed vaccination scar, and an

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 8, 1947.

atypical rash. Le Bar had a successful vaccination in childhood and an unsuccessful one about a year previous to his leaving Mexico. Biopsy of the skin lesions was done, but no Guarnieri bodies were seen in formalin-fixed material. Later when the diagnosis of smallpox had been made in contacts, other sections from the same biopsy material showed the characteristic Guarnieri bodies of smallpox.

The diagnosis of toxic eruption due to a drug was made because the patient had taken medication which often causes a rash in susceptible individuals. On March 10 he died, and at autopsy multiple hemorrhages were found throughout the viscera. The liver was soft and friable, the spleen was large, and there were hemorrhages in the medulla of the adrenal glands. The lungs were also hemorrhagic, and on microscopic section alveolar hemorrhages were noted.

Among the patients who were in Wil-

lard Parker Hospital at the same time as Le Bar were Ismael Acosta, age 27, with mumps, and a 22 months old girl suffering from croup. Neither of these patients had ever been vaccinated, and both were discharged from the hospital upon recovery from their illnesses. On March 19, the girl developed a rash and on March 21 was readmitted to Willard Parker Hospital with a diagnosis of chickenpox. On March 22 Acosta, who was working at Bellevue Hospital, also developed a rash and was admitted to the dermatology ward of that hospital. On March 27 he was transferred to Willard Parker as a case of possible chickenpox.

Because in neither instance did the rash appear to conform to that of chickenpox, a tentative diagnosis of smallpox was made. This diagnosis was later confirmed by Dr. Joseph Smadel at the U. S. Army Medical School Laboratory and Dr. Robert F. Parker at Western Reserve University. Fluid

taken from the pustules of the two patients had been sent to them for laboratory examination. The material had been inoculated into the chorio-allantoic membranes of chick embryos. The report received showed that the membranes were covered with numerous lesions characteristic of smallpox infection. Complement-fixation of these membranes against a known positive anti-vaccinal rabbit serum was strongly positive.

The moment that smallpox was suspected, all employees and patients at the Willard Parker Hospital were vaccinated. The case of Eugene Le Bar was carefully reviewed, further study of the skin lesions was made, and the diagnosis of smallpox was established. It was now evident that he had been the source of infection for the other two cases. All of them had been in the same building, Le Bar and the baby on the ground floor and Acosta on the seventh floor. A search was made for all possible contacts with Acosta and the baby. These were immediately vaccinated, as well as employees and guests still present at the hotel at which the Le Bars had stayed. Guests who had left the hotel were located and were instructed to be vaccinated at once.

A boy $2\frac{1}{2}$ years of age, never vaccinated, who was in Willard Parker Hospital for whooping cough during Le Bar's stay, developed a rash on March 27. The diagnosis of smallpox in this case was confirmed by the laboratory.

On April 6, Acosta's wife, age 26, was admitted to Willard Parker Hospital with fever. She developed a rash the next day, and died of smallpox on April 12. Although Mrs. Acosta was vaccinated as soon as it was known that her husband had smallpox, she apparently had already contracted the disease.

Three men, ages 43, 57, and 60, all patients at Bellevue Hospital when

Acosta was there, developed rashes on April 10, 11, and 13. A diagnosis of smallpox was made in each of these cases and the patients were removed to Willard Parker Hospital.

A 4 year old boy who was discharged from Willard Parker on March 10, the day of Le Bar's death, went to a convalescent home in Milbrook, N. Y. While there, he developed a rash which was subsequently diagnosed as smallpox. He was the source of 3 other cases at the home—a nun, age 62, a 5 year old boy, and a 2 year old girl. Thus the outbreak consisted of 12 cases, 9 originating in New York City and 3 in Milbrook, N. Y. Of the 9 in New York City, 2 died.

THE VACCINATION CAMPAIGN

The diagnosis of smallpox in the case of Acosta was confirmed by Dr. Smadel in a telephone call from Washington, D. C., on April 4, 1947. The U. S. Public Health Service was immediately notified and steps were taken by them to trace the route of the bus on which the Le Bars had traveled, in order to discover whether additional foci of infection had been set up. Mrs. Le Bar was located by the U. S. Public Health Service in Maine, where she had gone after her husband's death. Fortunately, she had been vaccinated against smallpox when she visited her husband at Willard Parker Hospital. She was in good health and had a successful vaccination. Follow-up along the bus route revealed that there were no cases of smallpox in those areas traceable to Le Bar. A plan for vaccinating all the people in the city was drafted by Health Department officials in conjunction with Commissioner of Hospitals Dr. Edward M. Bernecker and members of his staff. The Health Department's Bureau of Laboratories was placed on an emergency work schedule. A statement concerning the situation was given to the press, and messages were broadcast

I. A.—27 years old—smallpox on eighth day of the disease.

Infant 22 months old—smallpox on tenth day after onset.

over the radio urging all New Yorkers to be vaccinated without delay. Vaccination clinics in the Health Department headquarters building, in all Health Department health centers, and in the city hospitals were kept open day and night, seven days a week.

Two hundred and fifty thousand individual doses of smallpox vaccine were available for immediate distribution by the Health Department laboratories. Bulk for an additional 400,000 units was on hand. The Bureau of Laboratories began immediate packaging of the bulk, permission having been granted by the U. S. Public Health Service to put this vaccine up in vials containing fifty doses each. The United States Army and Navy sent several hundred thousand units of vaccine gathered from all parts of the country. Since millions of units were needed to vaccinate the people in New York City, and this amount was not available, Mayor O'Dwyer called an emergency meeting at his office. Present at this meeting were representatives of the manufacturers of vaccine, members of the Health Department staff, and Dr. Thomas M. Rivers, Director of the Rockefeller Institute for Medical Research, and member of the Board of Health. At the urgent request of the Mayor, the manufacturers went on a 24 hour schedule packaging their bulk vaccine and diverting all available supplies to this city. Retail pharmacists coöperated in distributing vaccine to private physicians. Vaccine supply stations were set up at a centrally located police precinct and at the Health Department.

Vaccination stations were set up in all police precincts, in addition to Health Department buildings and municipal hospitals and clinics. There was a total of 179 city installations being used for vaccination. Practically every hospital in the city set up a special clinic where vaccinations were given to all who applied, free of charge. The

vaccine was furnished by the Health Department and was administered by doctors on the hospital staff. Many community organizations set up local centers staffed by volunteer physicians and clerks. Labor and industry coöperated by establishing vaccination stations in factories, offices, and union headquarters. In some cases, their own physicians did the vaccinating; in others, it was performed by Health Department personnel. The stations maintained by the city remained open from 9 a.m. until 10 p.m., including Saturdays and Sundays. On April 26, those at the police precincts were discontinued, and on May 3 all other stations were closed.

In a period of less than a month more than 6,350,000 people were vaccinated in New York City, over 5,000,000 of them within the two week period following the appeal for universal vaccination made by the Mayor. Never before had so many people in one city been vaccinated in such a short time and on such short notice. Thanks are due to the press and radio for giving so generously of their space and time to bring necessary information to the public. Had it not been for them and for the intelligent coöperation of the public and the generosity of private physicians and volunteer workers, notably from the American Red Cross and the American Women's Voluntary Services and former Air Raid Warden groups, it would have been impossible to have achieved this remarkable record.

smallpox and 20 deaths. These cases were all attributable to a soldier stationed in Japan who had developed smallpox aboard ship en route to Seattle.

During the period 1900 to 1929, epidemics of virulent smallpox were reported throughout the United States. Notable among these were the outbreaks in 1921 in Denver and Kansas City, when the former city reported 924 cases and 37 deaths, and the latter 943 cases and 160 deaths. In 1924, Detroit reported 1,610 cases and 163 deaths. In 1901, an epidemic of smallpox in New York City resulted in 1,959 cases and 410 deaths. Had the same rate prevailed in the 1947 outbreak, there would have been 4,310 cases and 902 deaths.

All of the cases of smallpox that occurred in New York in April, 1947, were of the virulent type which usually has a fatality rate of 40 per cent in children and 20 per cent in adults. Because of the virulence of the disease and its high communicability, it is little short of remarkable that there were only 12 cases in the entire outbreak.

One of the most difficult problems facing health officials is the control of the spread of the disease through unrecognized mild cases in persons who have retained some immunity from vaccination in infancy. These mild missed cases can be the source of virulent smallpox in unvaccinated persons and in those who have completely lost their immunity from former vaccinations.

VACCINATION AND IMMUNITY

Of the 12 patients in the recent outbreak, only 3 had ever been vaccinated. These 3 had received protection more than forty years previously. There is no evidence that any person has a natural immunity to the disease. The length of time that immunity lasts in a vaccinated individual varies considerably. It may be just a few months or

many years. The soldier who brought smallpox to Seattle in 1945 was returning from the Pacific theatre of war and had been vaccinated as were all persons in the armed forces. Many individuals in New York City who had been vaccinated only a few years before the present outbreak had accelerated reactions when revaccinated, and in some cases, primary takes. Several physicians reported that children, 2, 3, and 4 years of age, who had been vaccinated in infancy, showed primary takes when revaccinated. It is therefore apparent that whenever a case of smallpox occurs in a community, the only safe procedure is for every person in that community to be vaccinated without delay. The vaccination procedure recommended and practised by the Health Department was the multiple pressure method.

SEQUELAE

Whenever a large-scale vaccination program is undertaken, there is always the possibility that there may be some unfortunate complications. Every health officer is aware of this, but also knows that it is a risk which must be taken if there is to be universal protection.

Rumors run riot during a vaccination campaign. Many persons with chickenpox or with simple skin eruptions are thought by their friends to have smallpox. The Health Department received innumerable telephone calls reporting cases of smallpox, which upon investigation proved to be chickenpox. Likewise, many people who, several days after they had been vaccinated, became ill with any one of a variety of symptoms, called the Health Department to find out if the vaccination was responsible. In New York City, there are thousands of people who become ill, and about two hundred of them die every day. Since practically every person in New York City had a recent vaccination, it was inevitable that some of them would become ill and would die. Vac-

Disease spread from Eugene Le Bar to Ismael Acosta and two children. Acosta in turn infected his wife, who died, and four others. One child who was infected by Le Bar passed virus to two children and a nun in Millbrook, N. Y.

cination does not stop the normal course of events. Neither should vaccination be blamed for a death from cerebral hemorrhage, nephritis, or coronary occlusion.

It is well known that encephalitis occasionally follows vaccination. When it is due to vaccination, it almost invariably occurs 11 to 14 days later. It may occur up to 30 days later, but this is exceedingly rare. From the beginning of April, when the vaccination program was instituted, until the second week of June, 50 possible cases of encephalitis were reported to the Health Department. Four of these cases were ruled out as definitely not encephalitis. In the remaining 46 cases, the diagnosis was considered probable. Eight of these 46 individuals died.

A diagnosis of post-vaccinal encephalitis can be made with certainty only after microscopic examination of the brain tissue. Brain tissue of the 8 fatal cases was examined, and in none of them were the characteristic lesions of post-vaccinal encephalitis found. Autopsy showed that 2 of the deaths were caused by tuberculous meningitis, 1 by a brain tumor, 1 by coronary sclerosis, and 4 probably by cerebral lesions. The Health Department has had no proof of any death due to post-vaccinal encephalitis in its vaccination campaign.

Although none of the cases of encephalitis was found to be associated with vaccination, 3 deaths did occur from other complications. A 66 year old man died as a result of septicemia

which followed an infection of the vaccination. Two infants, age 8 months and 4 months, who had eczema, developed generalized vaccinia as a result of contact with persons who had been recently vaccinated.

Tragic as these incidents were, it must be borne in mind that had vaccination not been carried out on such a large scale, there very likely would have been thousands of cases and hundreds of deaths.

CONCLUSION

Every health officer must be aware that no community can be considered safe from smallpox even though there has not been a case of it for many

years. New York City had not had an outbreak for twenty years. Universal vaccination is the only safeguard. The period of immunity conferred by vaccination varies with each individual. Lasting protection can be assured only by periodic revaccination at intervals from five to ten years, always with a vaccine known to be potent and properly administered. Failure to react to a vaccination indicates an impotent vaccine or poor administrative technique. Contrary to popular belief, it does not indicate that the person is immune. Just as soon as a case of smallpox is suspected in a community, every effort must be made to have everyone vaccinated without delay.

Control of Cross-Infections in Infants' Wards by the Use of Triethelyene Glycol Vapor*

CLAYTON G. LOOSLI, M.D., MARGARET H. D. SMITH, M.D.,†
ROSS L. GAULD, M.D., F.A.P.H.A.,‡ OSWALD H.
ROBERTSON, M.D., AND THEODORE T. PUCK, Ph.D.

*Department of Medicine, the University of Chicago; Department of Pediatrics;
and School of Hygiene and Public Health, Johns Hopkins University,
Baltimore, Md.*

THE problem of prevention of cross-infections in infants' and children's wards is a serious one.^{1, 2} Solution is made difficult by the lack of information concerning the relative importance of various means by which pathogenic organisms may be acquired. The air-borne route is recognized as one of the important modes of spread of etiological agents causing secondary respiratory tract, skin, and wound infections in hospitals. Four methods have been employed to keep the bacterial and virus content of the air in wards below the infective level. These are (a) increased ventilation and mechanical barriers,^{3, 4} (b) dust suppression by the treatment of floors and bedclothes with oil,⁵⁻¹⁰ (c) ultra-violet irradiation,^{1, 11-19} and (d) chemical disinfection of air with glycol vapors.^{20-23, 26-31} Several investigators have reported limited success in

reducing cross-infections in children's wards by means of irradiation of the air, but mechanical barriers, dust suppressive measures, and chemical disinfection with glycol vapors have not been evaluated in this respect.

In 1941 Robertson and associates first reported laboratory studies on the germicidal properties of propylene glycol when dispersed into the air as aerosols and vapors.^{20, 21} Since this time, studies by various members of the Commission on Air-borne Infections under the direction of Robertson have been concerned with (a) further observations on the disinfecting properties of glycols, particularly of triethelyene glycol vapor,^{22, 32, 33} (b) the mechanism of germicidal action of these compounds,²³⁻²⁵ (c) the toxicity of glycols on repeated injection and on continuous inhalation by rats and monkeys,^{23, 34} (d) the development of apparatus for the vaporization and control of the glycol vapor in the air,³⁵⁻³⁷ (e) physico-chemical properties of glycol vapor in the atmosphere which influence the extent of its condensation on bacterial droplets,³⁸⁻⁴⁰ and (f) the bactericidal activity of triethelyene glycol vapors in the atmospheres inhabited by human beings under different conditions of

temperature, relative humidity, and dust control.²⁶⁻²⁸

Likewise, several reports by Bigg and coworkers since 1944 have dealt with the (a) development of apparatus for the dispersion of glycol vapors,⁴¹⁻⁴³ (b) the possible fire hazards connected with the use of glycols as germicidal agents,⁴⁴ (c) the lethal action of glycol vapors on spore-forming bacteria⁴⁵ and fungi,⁴⁶ and (d) the epidemiological observations on the use of triethylene glycol vapors as a means of controlling respiratory tract infections among military personnel.^{47, 48} Other workers in this country,⁴⁹⁻⁵² Canada,⁵³ and England⁵⁴ have studied various aspects of the problem of the use of glycol vapors for the disinfection of air.

The present study was organized to evaluate further the use of triethylene glycol vapor as an air disinfecting agent for the prevention of cross-infections in hospital wards. Although previous studies by the Commission had demonstrated that the maximum effectiveness in ridding the atmosphere of bacteria is obtained when the action of glycol vapor is supplemented by dust control measures, it was decided to use only glycol vapor in this test, in order to assess the usefulness of this method alone. Because of the high incidence of cross-infections and the opportunity to control the activities of the patients, infants' wards were considered most suitable for conducting such an investigation. At the invitation of Dr. Edwards A. Park, the present study was made on the infants' wards of the Harriet Lane Home, Johns Hopkins Hospital. The investigation extended from November 15, 1945 to May 1, 1946.

MATERIALS AND METHODS

Wards—The test (east) and control (west) wards were comparable in size and shape (20 x 60 ft.). Each was divided into cubicles with walls extending from the floor to a height of

approximately 7 ft. (6 ft. 10 in.) Space was provided for 16 beds in the test and 18 in the control ward. The wards were heated by hot water and ventilated by opening windows. Figure 1 is a sketch of the test ward, showing, by numbers, the cubicles and the position of the apparatus employed in the maintenance and control of relative humidity and glycol vapor concentration in the air.

Maintenance and Control of—

a. Relative Humidity and Temperature: The apparatus employed was that developed and previously used by the Commission on Air-Borne Infections during studies on the control of the bacterial content of the air in Army hospital wards.^{26-28, 26, 37} An instrument for recording continuously the wet and dry bulb temperatures* was installed in both wards. Adequate humidification of the air of the wards was secured by introducing steam from the heating pipes after passage through a suitable muffler. A solenoid valve placed in the steam line and controlled by a Friez humidostat regulated the steam output to maintain a relative humidity of 40 per cent. One such humidifying system sufficed for the control ward, but two were needed for the test area in order to provide sufficient water vapor promptly in the vicinity of each glycol vaporizer. The temperature of the wards was controlled by opening the windows and manually turning radiators off and on.

b. Concentration of glycol vapor in the air: Two Research Corporation Glycol Vaporizers† were employed in the test ward, placed one on each side of the large utility room as shown in Figure 1. Appropriately placed fans mounted near the ceiling produced an even distribution of water and glycol vapors throughout each space. To avoid a direct draft on

* Taylor Instrument Company, Chicago, Ill.

† A single vaporizer of this size would have been sufficient if the ward had not been constricted by the utility room.

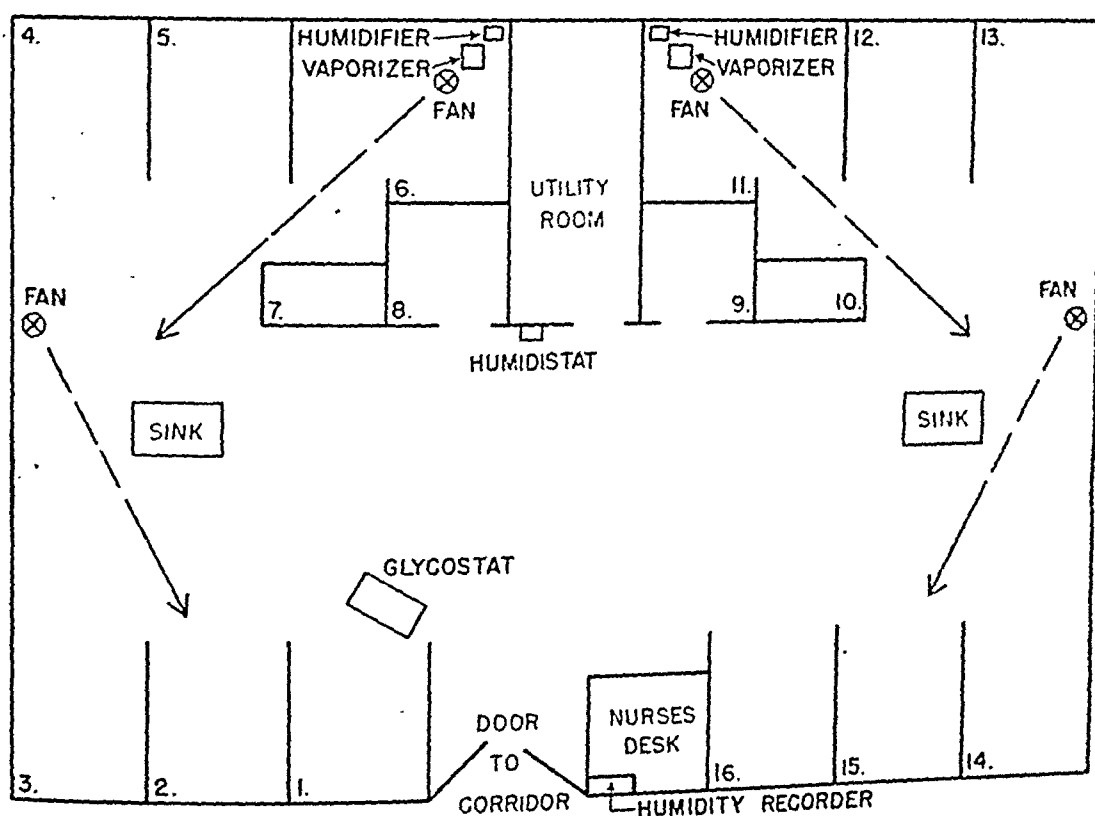

FIGURE 1—Test ward showing cubicle arrangement and position of apparatus for maintenance and control of relative humidity and glycol vapor concentration in the air

the infants, these fans* were run at moderate speed and directed slightly upward. The direction of the air currents is shown by the arrows in Figure 1. The number of fans required for adequate mixture of the ward atmosphere was at least twice that needed for an unobstructed space. The output of the vaporizers was regulated by means of a glycostat which was placed in the room as shown in Figure 1. An Esterline-Angus milliammeter connected with the glycostat gave a continuous record of the concentration of triethylene glycol vapor in the air which was maintained below the fog level. The only occasions that a glycol fog occurred despite glycostat control were when the relative humidity was increased by the sudden release of large quantities of steam from the sterilizers in the ward utility room. Atmospheric supersaturation with glycol under these conditions was due to the fact that as the relative humidity in-

creases the amount of glycol vapor capable of being held in the air decreases progressively until finally condensation occurs.²³⁻²⁵

Bacteriological Methods—During the course of study, frequent surveys were made of the bacterial flora of the nasopharynges of the infants, noses and throats of the hospital personnel, and air and dust of the wards. Particular attention was paid to the presence of group and type-specific beta-hemolytic streptococci and type-specific pneumococci. Close attention was also directed toward the presence and spread of a previously undescribed respiratory tract pathogen of the Friedlander-aerogenes group, a Gram-negative bacillus, which "quelled" in types 23 and 32 pneumococcal typing sera.

a. Patients: Two nasopharyngeal cultures were obtained from each infant on admission and one, thereafter, on every Monday and Thursday, and one at the time of discharge. All patients devel-

* Reynolds Fan Company, Chicago, Ill.

oping secondary infections of the respiratory tract, skin, and wounds were also cultured. The nasopharyngeal cultures were taken in the following manner: A small copper wire swab, moistened in fresh beef-heart infusion broth* to which 2 per cent defibrinated sheep blood was added, was inserted first through one nostril and then the other nostril into the nasopharynx. It was allowed to remain there for 10 to 15 seconds, removed, smeared on a blood (5 per cent sheep) agar plate, and inserted again into the blood broth. The blood agar plate was streaked in the laboratory. Both broth and plate cultures were incubated for 18 hours at 37°C. The plates were examined for beta-hemolytic streptococci. If present, they were picked and transferred to tryptose phosphate broth for grouping and typing after the manner of Swift, Wilson, and Lancefield.⁵⁵

All broth cultures were examined by direct typing for pneumococci and Gram-negative bacilli. Negative cultures were injected intraperitoneally into mice ($\frac{1}{2}$ ml.) which, if they did not die, were killed in 48 to 72 hours and the peritoneal contents examined for the above organisms. Both broth and plate cultures were made from skin and wound lesions with the swab technique, after which they were examined in the above manner.

b. *Hospital personnel*: Nose and throat cultures were taken routinely once a week on the professional staff, nurses, and ward attendants. For several weeks, from January through March, nose and throat cultures were taken on visitors (parents, friends, etc.).[†] The cultures were then examined as described above

for pneumococci, hemolytic streptococci, and Gram-negative bacilli.

c. *Environment*: Semi-weekly bacteriological analyses of the air on the test and control wards were made employing the Folin-bubbler-sampler⁵⁶ and blood-agar open plate, methods previously used by the Commission on Air-borne Infection in other studies.²⁶⁻²⁸ The samples were taken on the test and control wards on consecutive days (Monday and Tuesday, Thursday and Friday), usually from 7:30 a.m. to 9:30 a.m., during the period of maximum activity, such as bed making, bathing, and feeding of infants, and floor sweeping.

At the time of taking the air cultures, two Folin-bubbler-samplers were set up simultaneously, one at each end of the ward. Each sampler was run for 20 minutes, pulling air through it at the rate of 1 cu. ft. per minute. A total of from 10 to 12 such samples were taken during one morning's run. Aliquots of the bubbler broth were then plated for total bacteria (0.5 ml.) and for hemolytic streptococci (2.0 ml); 1-750,000 Gentian violet was added to the latter to inhibit the growth of other organisms.⁵⁷ Gentian violet was added to the remaining broth which was incubated for 18 hours at 27°C. and inoculated intraperitoneally into mice for isolation of pneumococci.

Open blood agar plates (without gentian violet) were placed on the bedside tables and exposed to the ward air for 1 hour (7:30 to 8:30 a.m.) and others containing gentian violet were exposed from 7:30 to 11:30 a.m. Counts for total bacteria as well as for hemolytic streptococci were made, and the latter picked for grouping and typing. Streptococci picked from the plates were inoculated into blood broth, and incubated at 37°C. for 18 hours, after which 0.5 ml. of the culture was inoculated intraperitoneally into mice for the isolation of pneumococci. The specific encapsulated Gram-negative bacillus referred to

* Containing gentian violet 1-750,000. This concentration showed no germicidal effect on pneumococci, hemolytic streptococci, or the Gram-negative bacilli.

† Visitors were admitted to the ward only on the day of admission and once a week on Sundays from 2:00 to 3:00 P. M.

above grew also on the gentian violet plates as a mucoid translucent colony. These colonies were counted, picked, and set up directly in types 23 and 32 pneumococcal typing sera for identification.

Ward Technique of Handling Patients

—In so far as possible, an aseptic technique was followed when caring for the infants. Gowns, hung in the open ward at the entrance of each cubicle, were worn by the nurses and attendants when the infants were fed, dressed, changed, and had their beds made. Masks were also worn when very young infants were handled. Gowns were changed and hands washed thoroughly before and after caring for each patient. Attendants with upper respiratory infections were isolated during the acute phases of illness or required to wear masks while on the wards. In the case of emergencies and during ward rounds these techniques were not always carried out.

Patients—Infants from 1 day to 2 years of age were admitted to the wards with a wide variety of medical and surgical illnesses. There were 130 patients in the control and 140 in the test wards who stayed a sufficient length of time (5 days) to be included in the study. They were admitted, as far as possible, alternately to the test and control wards. In a few instances, some cases were shifted purposely from one ward to another. As shown in Table 1, the mean age of the patients and the time spent in the hospital were comparable on the two wards.

Approximately half of the patients had respiratory tract or skin infections at the time of admission. The results of the admission nasopharyngeal cultures are shown in Table 2. There were only 3 cases admitted to the wards with cultures positive for hemolytic streptococci. Actually, one of the cases on the test ward was a transfer from the control ward with the positive culture. The majority of the infants showed positive cultures for one or more types

of pneumococci. The most prevalent types, which made up approximately 50 per cent of the strains isolated, were 6, 14, 19, and 23. Twenty-four additional pneumococcal types were isolated (Table 2).

Sulfonamide and Antibiotic Therapy
—Soon after the study began it became evident that consideration would have to be given to the use of sulfonamides and penicillin on the wards. These drugs, although of great benefit to the patient because of their antibacterial activity, constituted a factor which must be considered in the analysis of the findings if the experience of the two wards was to be compared. Accordingly, the experience of the patients in each of the two wards was divided into: (a) hospital days with no chemotherapy, and (b) hospital days with chemo-

therapy. This allowed not only a comparison of the effect of the triethylene glycol vapor, but also gave some measure of the role of these antibiotics in the prevention of new infections while on the wards.

An analysis of the experience of the two wards with respect to the use of antibiotics is shown in Table 3. It will be seen that 40 per cent of the experience of the patients on the control ward and 45 per cent of the experience on the test ward was with chemotherapy. This difference has been adjusted for in the analysis where the infection rates have been calculated per 1,000 hospital days, with and without chemotherapy (Table 5).

RESULTS

Vaporization of Triethylene Glycol—Vaporization of triethylene glycol was begun on the test ward November 7, 1945, and discontinued April 25, 1946. Observations on the incidence of secondary infections developing in the two wards were begun November 15, 1945, and continued until May 1, 1946. The concentration of glycol vapor in the air of the test ward varied from 55 per cent to 70 per cent.* Only on one or two occasions was the glycol apparatus turned off for more than a few hours during the whole period of study. The longest interval (8 hours) occurred at night when a bulb in the glycostat burned out and was not replaced until the following morning. The consumption of triethylene glycol was approximately 200 ml. per day.

Effect of Glycol on Personnel, Patients,

* Some trouble was encountered in the operation of the glycostat due to the marked dustiness of the ward air. It would gradually lose its sensitivity because of the accumulation of dirt on the reflecting surface of the rotating wheel. This made it necessary to reset the controls every two or three days to maintain the glycol concentration at the sub-fog level and to clean the glycostat about every ten days. On occasions, when the glycostat did not function well, it was set so that a visible fog was maintained to insure an adequate disinfecting concentration of glycol vapor in the air.

and Ward Environment—There were no major complaints from the attendants, nurses, or doctors who worked on the ward from a few days to several months. One or two nurses complained of headaches as a result of working on the ward when a visible glycol vapor fog was present. It was impossible to control the temperature adequately on the test ward and on occasions it would go as high as 85° F. with a R.H. of 40 per cent. At such times the ward was uncomfortably warm. There was no evidence of toxic effect on the respiratory tract or skin of infants who lived on the test ward from a few days to several weeks.

Due to the frequent release of large quantities of steam from the ward utility room, described earlier, glycol condensed on the windows and walls, which caused dirt to accumulate over a period of time. The condensation on walls and ceilings was greatly accentuated by the impingement of air currents from the four fans necessary to produce adequate mixing of the air in this constricted space. The unusually heavy dust content of the air added to the deposition of dirt. It should be pointed out in this connection that earlier installations of triethylene glycol in wards of similar size but having free circulation of air and a constant relative humidity were accompanied by no visible condensation of glycols on the walls or ceilings.²⁶⁻²⁸

control wards was analyzed on 43 different days during the period of study. As shown in Table 4, the mean number of patients, mean relative humidity, number of settling plates exposed, and number of cubic feet of air analyzed by the Folin-bubbler-sampler were essentially the same on the test and control wards. The mean per cent saturation of triethylene glycol vapor on the test ward was 60 per cent during the days of air sampling.

There were 31 per cent less bacteria recovered from the air of the test ward employing settling plates, and 70 per cent less employing the Folin-bubbler-sampler, than were recovered by these techniques, from the air of the control ward. The variation in the number of air-borne bacteria obtained from the air of the wards during the period of study is shown in Figure 2. There was no apparent reduction in the number of group A type 33 hemolytic streptococci in the air when an infant with generalized

eczema, secondarily infected with these organisms, was placed on the glycol ward.⁵⁸ The extent of contamination of the environment by the "tracer" organisms will be given in separate reports.^{58, 63, 64}

Infections Developing on the Wards—

All infections which developed in the infants on the two wards during the study period were classified as follows:

- Clinical infections:* These included all infections accompanied by two or more objective signs such as coryza, stuffy nose, red throat, red ear drums, draining ear, diarrhea, or vomiting; as well as those with symptoms of illness such as fever, fretfulness, or convulsions. Clinical infections were subdivided into non-specific and specific infections, depending upon whether or not it was possible to recover one of the three pathogens (pneumococci, hemolytic streptococci, or specific Gram-negative bacilli) from the nasopharynx, skin, or wound.
- Inapparent or non-clinical infections:*

FIGURE 2—Weekly bacterial counts from the air of test and control wards employing blood agar open "settling plates" (above) and Folin-bubbler-samplers (below)

These included all cases where there were no clinical manifestations of illness, but a pneumococcus, hemolytic streptococcus, or specific Gram-negative bacillus not previously isolated from the case was cultured during the semiweekly swabbing of the nasopharynx.

Table 5 compares the incidence of infections developing on the two wards during the course of the study. A comparison of the rate per 1,000 hospital days for nonspecific clinical infections shows a slight margin in favor of the test ward. Thus, rates of 6.1 and 7.5 per 1,000 were recorded in the test ward for those receiving and not receiving chemotherapy respectively as against comparable rates of 11.4 and 10.4 on

the control ward. These differences, however, are no greater than could be expected to occur by chance. It is interesting to note that this type of infection was only slightly, if at all, influenced by chemotherapy.

Specific bacterial infections occurred at the same rate among those receiving chemotherapy on the two wards. Among those not on chemotherapy the rates were 12.4 and 7.5 for the control and test wards respectively. This difference is well within the range of chance variation and no conclusions as to the efficacy of triethylene glycol vapor in preventing this type of infection is warranted on the basis of these results. It should be noted, however, that with bacterial in-

fections the incidence was significantly lower on both wards among those receiving antibiotics.

No differences were observed in the incidence of the inapparent infections on the two wards, nor was there any significant reduction in the occurrence of these infections due to administration of chemotherapy.

In Table 6 are listed the number and kinds of infections occurring on the test and control wards from which the data given in Table 5 are derived.

DISCUSSION

The apparatus employed in dispersing and controlling the concentration of glycol in the air of the test ward functioned satisfactorily during the period of study. This is shown by the fact that 70 per cent less bacteria, using the Folin-bubbler-sampler, were recovered from the air of the test ward than from that of the control ward. This reduction is essentially the same as that (60 per cent) reported by Hamburger, Puck, and Robertson²⁶⁻²⁸ in the streptococcal content of the air, when similar apparatus was employed in hospital wards in Army camps. Combining dust suppres-

sive measures with glycol vapors for the disinfection of air, they reduced the streptococcal count in the air of the test ward over 90 per cent, compared to counts attained during the control periods. No data are available as to the degree of reduction of air-borne pathogenic bacteria necessary to bring about a lowered incidence of infection.

In the present study, dust suppressive measures (oil to bedclothes and floors^{9, 10}) were not employed. This is reflected in the lack of any striking effect of the glycol vapor on the bacterial content of the air as shown by the open plate counts. On the basis of the probable mechanism of germicidal action of glycol vapors,²³⁻²⁵ it would not be expected that the bacteria in the larger particles which quickly "settle out" of the air onto the exposed blood-agar plates would be killed by the germicidal vapors. Thus, as pointed out by these investigators, oiling procedures should be employed along with the glycol vapors for the latter to function most satisfactorily.^{26, 27}

Bigg and associates^{47, 48} have applied the technique of chemical disinfection of air with glycol vapors to the problem

of control of respiratory diseases among military personnel. They compared the incidence of infections in a group of men (324) sleeping in glycol-treated quarters over a 6 week period, with the incidence among a control group sleeping in untreated quarters. Although there were 64 per cent less infections among the men billeted in the glycol-treated quarters during the last 3 weeks of observation, the reduction for the entire period was only 12 per cent. The number of carriers for hemolytic streptococci also became less in the group living in the glycolized quarters.

Harris and Stokes²⁹⁻³¹ observed the effect of propylene glycol vapor and, later, triethylene glycol vapor on the incidence of respiratory infection in a children's convalescent home. During the three year study they observed only 13 infections on the wards during the test periods, compared to 132 during the control periods. As pointed out by the authors, this study was made under highly favorable circumstances. The wards were essentially quiet ones with a limited amount of coming and going of visitors, professional and nursing staff. Very few of the children were acutely ill. Most of them were bedfast, providing very little contact with one another and opportunity for direct drop-let spread of infection.

Our study in the infants' wards at the Harriet Lane Home shows no such dramatic results as those reported by Harris and Stokes. However, the conditions for testing triethylene glycol vapors as a means of control of cross-infections were not so favorable. Harriet Lane Home is a teaching hospital for medical students, nurses, a large group of house staff and attending men, and there was continuous traffic by the personnel into and out of the wards for the greater part of the day. Many of the infants were acutely ill and often required intimate care by the attendant, nurse, or doctor. During emergencies,

cubicle isolation and aseptic techniques were sometimes broken. This situation existed equally on both the test and control wards. Thus, the conditions under which this study was conducted constituted an unusually difficult test for evaluating the use of glycol vapors for the prevention of hospital infections. Although the incidence of nonspecific and specific bacterial cross-infections was less among the infants on the glycol ward than among those on the control ward, the difference is not statistically significant. As indicated above, there were many opportunities for the spread of infections other than by the air-borne route. Recognizing this, the reduction in clinical infections which did occur on the test ward may represent that proportion which were air-borne and thus prevented by glycol vapor.

The question was often asked by interested visitors during the course of this study, how triethylene glycol vapor compares with ultra-violet irradiation as a means of preventing cross-infections in children's hospitals. Ultra-violet light has been employed for this purpose by McKhann, Steeger, and Long,¹ Barenberg, Greene, and Greenspan,¹¹ Greene, Barenberg, and Greenberg,¹² del Mundo and McKhann,¹³ Sauer, Minsk, and Rosenstern,^{15, 16} and Robertson, Doyle, and Tisdall¹⁹ with varying degrees of success. Brooks, Wilson, and Blackfan,¹⁴ on the other hand, report no effect of ultra-violet light in preventing respiratory infections on infants' wards. On the basis of the results of the above studies already cited and those of Wells,⁵⁹ Hart,⁶⁰ and others, the Council on Physical Therapy voted to accept ultra-violet lamps for disinfecting purposes.⁶¹ Hollaender,⁶² reviewing the problem of ultra-violet irradiation, emphasized that further studies following carefully the recommendations of the Council were necessary before this technique of air disinfection could be evaluated accurately. The results of

chemical disinfection of air with glycol vapors are encouraging but many more controlled studies under different ward conditions need be carried out before the relative merits of ultra-violet light and glycol vapors for air disinfection can be evaluated.

Although the extensive use of sulfonamides and penicillin was considered a complication as far as the primary purpose of this study was concerned, it was recognized that the administration of these therapeutic agents was now a general procedure and that they would be widely employed in any future ward study of this kind. The significantly low incidence of clinical, bacterial infections in the groups receiving antibiotics, compared to the rate among those not receiving drugs on both wards, shows that these antibacterial agents also acted prophylactically to prevent the pathogens from invading the host tissues, although they did not prevent implantation on the mucous membranes. Essentially no controlling effect by these drugs, however, was observed in the case of nonspecific clinical and inapparent bacterial infections. These observations emphasize that air disinfecting procedures as a means of preventing secondary bacterial infections must also be evaluated in relation to the simple, but sometimes expensive, therapeutic procedure of giving antibiotics for the duration of the child's stay in the hospital.

Space will permit but a brief statement of the epidemiological studies to determine the relative importance of different modes of spread of infections on the wards. Employing the hemolytic streptococcus, pneumococcus, and specific Gram-negative bacillus as "tracer" organisms, it was found that at certain times the ward environment (dust and air) became heavily contaminated with these pathogens. The source was usually found to be one or more of the ward patients with exudative skin infections or purulent otitis media in the case of

the hemolytic streptococcus, a chronic sinusitis or bronchitis with considerable nasal discharge and coughing in the case of the pneumococcus, and acute upper respiratory infections and diarrhea in cases where the Gram-negative bacillus was isolated from the throats and stools. Thus, the path of infections appeared to lead from patient to patient and from patient to attendant, nurse, visitor, and doctor. In rare instances was the course of the infection traceable to an adult. The data from which these observations were made will be the subject of separate reports.^{58, 63, 64}

SUMMARY AND CONCLUSIONS

A study was conducted on the control of cross-infections by the use of triethylene glycol vapor on the infants' wards of the Harriet Lane Home, Johns Hopkins Hospital, from October 15, 1945, to May 1, 1946. The test and control wards were comparable in size, physical set-up, number of patients, and kinds of primary diseases treated.

The apparatus employed was that used in previous studies by the Commission on Air-borne Infections, Army Epidemiological Board, for the disinfection of air with glycol vapors in hospital wards in army camps. Under the conditions of the ward environments at the Harriet Lane Home, the dispersal and control of the glycol vapor was satisfactory. The extreme dustiness of the ward air (in the absence of the use of dust suppressive measures) necessitated frequent cleaning of the glycolstat to insure its proper functioning. During the period of study, the concentration of glycol vapor in the air of the test ward varied from 55 to 70 per cent.

There were no complaints from the attendants, nurses, or doctors who worked on the glycol wards. No injurious effect was noted on the respiratory tract or skin of infants who were on the test ward for several weeks to months.

Employing settling plates and the

Folin-bubbler-sampler, there was a consistent and significant reduction (31 and 70 per cent respectively) in the number of bacteria isolated from the air of the glycol ward when compared to the numbers isolated from the air of the control ward.

On account of the general use of chemotherapy, both for prophylaxis and treatment, it was necessary to consider this factor in the analysis of the data. A comparison of the rate of nonspecific clinical infections (URI) per 1,000 hospital days showed a slight margin in favor of the test ward. The difference, however, was no greater than could be expected by chance. These infections were only slightly, if at all, influenced by chemotherapy.

The rates per 1,000 hospital days of specific bacterial infections among those not receiving chemotherapy were 12.4 and 7.5 for the control and test wards respectively. This difference is within the range of chance variation, and no conclusions as to the efficacy of triethylene glycol in preventing this type of infection is warranted on the basis of these results.

Specific bacterial infections occurred at the same rate among those receiving chemotherapy on the two wards and was significantly lower on both wards than among those not receiving antibiotics.

Many more similarly controlled studies under different conditions of ward environments need be done to evaluate further the use of glycol vapor as a practical means of preventing cross-infections in hospitals and to compare its relative effectiveness with other methods of air disinfection (ultra-violet light and dust suppressive measures) and the prophylactic use of chemotherapeutic agents.

ACKNOWLEDGMENT—The authors wish to express their appreciation for the wholehearted cooperation of Dr. Edwards A. Park, Professor of Pediatrics and Pediatrician-in-Chief of the

Johns Hopkins Hospital; Dr. Alan M. Chesney, Dean of the School of Medicine, Johns Hopkins University; Dr. Edwin L. Crosby, Director of the Johns Hopkins Hospital; Helen Schnetzer, Head of Pediatric Nursing, Harriet Lane Home; Drs. Alexander J. Schaffer and Horace L. Hodes, Associates in Pediatrics and Attending Physicians at the Harriet Lane Home, the House Staff, and the Assistant Supervisors of Nursing at the Harriet Lane Home.

The authors also take pleasure in acknowledging the assistance on the wards of Nurses T. Aufhauser and D. H. Sinclair, and in the laboratory of J. Cline, C. M. Gonyea, I. Krimminger, L. V. Nelson, M. H. Ritter, and R. Kley.

Opportunities for the Engineer in Public Health*

ROBERT N. CLARK, F.A.P.H.A.

Chief Public Health Engineer, Tennessee Valley Authority, Chattanooga, Tenn.

THE opportunities for the engineer in the field of public health rest upon the need for the sort of service he can do, the analysis of problems, the research, the ingenuity in devising solution, the techniques of applying engineering equipment and methods, all with due regard to good economy and good organization. However, the opportunities for the engineer depend as much, or more, upon his personal characteristics, his imagination, his initiative, his energy, his intelligence, and his attitudes. It is up to him to develop his opportunities, not only as they knock on his door, but as he seeks them out. In the field of public health, the most effective development of an opportunity rests mainly on one personal attribute, a common ingredient in all successful public health workers, whether engineers, epidemiologists, nurses, or others, and that is a public health consciousness.

Not everyone has this attribute. Many public health workers become so immersed in a limited phase of a problem, so intrigued with complications or challenges to their technical ability, that they incline to overlook simple and elementary measures that have an important bearing on public health. Physicians are apt to think in terms of cases, engineers in terms of specialized equipment, and they both may lose

sight of a dominant element of their work. Recently, Dr. Haskell, in commenting on factors leading to unsatisfactory results of a milk sanitation program, stressed the need for just plain cleanliness. He stated that although modern milk sanitarians could discourse learnedly on the application of electronics to milk pasteurization, he doubted if more than a small percentage of them could take a milking machine apart and put it together again, and that an even smaller percentage carried with them a rod to probe the tubing. This has a familiar sound. How many engineers understand very thoroughly the action of anion and cation exchangers, who consider it beneath their interest to look for lipstick on drinking glasses or to check the chlorine in the cold water rinse of some beer joint? The public health attitude, the perception of hazards, and the conception of their impact on groups of people, is the first essential in developing opportunities in public health.

The interpretation of the term "public health engineer" is frequently much too narrow. Generally, it is applied to an engineer associated with an official public health agency, who is concerned almost solely with inspection and with the enforcement of laws and regulations. Such a concept does not consider the important contribution of four other groups, without whom the health department engineer would be almost helpless.

First are professionally trained

* Presented before the Engineering Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 10, 1947.

people responsible for the operation of engineering works. The chief operator of a municipal water works, the industrial engineer who runs a plant to remove objectionable pollution from factory wastes, the superintendent of a sewage treatment plant, all make a definite contribution to the protection of the public health. With the official agencies, this group forms a team, each member of which is reliant upon the other for full effectiveness. The health department cannot keep an inspector in every water plant, every sewage plant, every milk plant, or in fact in any such place, all of the time. The operating agency has a responsibility for careful compliance with established health standards, and the excellence of a public health program depends largely upon the excellence of operating personnel. Experience has shown repeatedly that poor operation can nullify the best of planning and an otherwise superior program.

However, another group of engineers is essential to the team—if the health department engineer must depend upon the operator, the operator must in turn depend upon the designing engineer to furnish him with a plant capable of performing its function. The idea is often expressed that a consulting engineer should be required to operate each new plant which he designs for perhaps a year, the reason being that he should develop detailed knowledge of the operator's problems. The idea is good, in that it not only leads toward improvements in design, but also emphasizes the dependence of the operator upon the designing engineer.

Quite a similar relationship exists in the case of the manufacturer of equipment. In fact, in milk pasteurizing plants and food establishments, the equipment people almost entirely supplant the designer, and such establishments are frequently built around more or less standardized units of equip-

ment. Even in the fields of water and sewage treatment, traditionally the stronghold of the consulting sanitary engineer, the overall engineering designs are greatly influenced by choices of equipment. This should stimulate the manufacturer, for it develops an element of competition and new and improved equipment is likely to follow.

Behind all of these groups stands another, which has a profound influence upon the entire field of public health engineering. It is a certain fact that the best trained personnel will turn in the best program and, conversely, poorly trained individuals can wreck a program at almost any point. Great stress is laid upon the educational qualifications of engineers, and upon in-service training of operators; and the proven benefits of this sort of program are very great. The group which furnishes instruction in public health engineering, the teachers in our educational institutions, are a fundamental part of a public health organization and exert a dominant influence throughout the whole field.

The effectiveness of each group, the health department engineers, the operators, the equipment manufacturers, the consulting engineers, and the teachers, increases in proportion to their understanding of and coöperation with all of the others. The teacher who has lost contact with field problems, or the equipment man who does not understand the basic principles of public health, are largely ineffective in promoting a sound program. All together, when motivated by a common goal, namely, the protection of the public health, these several groups can and do form a unified association, each playing a vital part.

With this broad concept of public health engineering, the many opportunities for trained engineers become quite apparent. The opportunity for any one is apt to lie in the field of his

greatest interest and talent. Within each sphere of activity there are many critical problems to be considered. There is need for basic research, some of relatively simple nature, but which has just never been tackled effectively, such as the effect of polluted water on bathers, and with that a sound criterion for bathing water quality. There is need for development and improvement of equipment, as is illustrated in the new technique for disposal of human wastes from railroad passenger cars; there is need for effective training of personnel where opportunities for an effective display of leadership are very great; there is need for constructive activity in all phases of public health engineering, not only in conventional sanitation, but in the fields of malaria control, industrial hygiene, and other areas of environmental sanitation. These and similar opportunities are awaiting constructive development. The highest development can probably be

attained by the closest possible association between groups; by a recognition of the principle that one good man can do a good job and another good man can also do a good job, but both together can do more than twice as good a job. That extra factor which is introduced as a result of joint effort is important, particularly when two widely different viewpoints converge upon a single problem.

One public health engineer may be fitted for teaching, another for selling, a third for operation and management, but all will find a sound development and a useful outlet for their abilities if they can keep forever in their minds and attitudes the public health consciousness; that their skill lies, not only in the mastery of complex and difficult problems, but in the ability to perceive hazards to the health of groups of people and to reduce or eliminate such hazards by the application of engineering methods.

An Epidemic of Mild Gastroenteritis of Unknown Etiology Presumably Spread by Contaminated Eating Utensils

M. ALLEN POND, F.A.P.H.A., AND JOHN S. HATHAWAY, M.D.

Departments of Public Health and University Health, Yale University, New Haven, Conn.

INTRODUCTION

Extent of Outbreak—This is the report of an outbreak of 64 known cases of nausea, vomiting, and diarrhea in a graduate school population of 322 adults of both sexes, of whom approximately 200 eat regularly in one dining hall. The infecting organism is unknown. The information used here was obtained by interview with 44 persons and from questionnaires returned by 112 others. The attack rate was 41 per cent in this group of 156 individuals, all of whom had eaten in the refectory mentioned.

Clinical Findings—During this outbreak, there were 3 cases severe enough to require infirmary admission. Each of these complained of nausea, vomiting, and diarrhea. In addition, 1 had general malaise. Their admission temperatures of 101° F., 104° F., and 100° F., returned to normal in 12, 24, and 36

hours respectively. These 3 cases presented no unusual findings, no evidence of marked dehydration, and, except for fever, no pronounced symptoms of toxicity. Two of these cases were admitted on April 13 and the third on the 18th. For each, symptoms appeared first on the day of admission.

Other than these 3, none of the patients was seen by a physician, although some had been confined to bed.

Chronology of the Outbreak—Data on the dates of onset and symptomatology for all cases are presented in Table 1 and Figure 1. When studying these data, it should be noted that the school had reopened after the spring recess on Thursday morning, April 10, 1947, and that no meals were served in the refectory on Sunday, April 13.

The curve suggests a primary source, or sources, of infection between April 10 and April 12. Nearly two-thirds (61

per cent) of the cases occurred on April 12 and 13, 11 per cent on April 10 and 11, and 28 per cent (delayed cases or secondary cases) between April 14 and 18. It does not seem likely, however, that infection at any single meal can have been responsible for the entire outbreak. We do not know the incubation period of this disease; but if we assume 2–38 hours, 39 per cent of the cases could have been caused by infection at the evening meal of April 12; while 34 per cent must have been caused before that meal. Infection at more than one meal on April 11 and 12 seems probable.

General Epidemiological Investigation—Reference to our daily epidemiological records made it clear that there was no concurrent increase in the incidence of gastrointestinal infection elsewhere in the university. Nor was any phenomenon of the kind noted in the community at large. On other grounds,

too, there was no reason to suspect generally distributed supplies such as water or milk.

Water for the school is taken from a public distribution system. Treatment consists of storage, slow sand filtration, and break-point chlorination, and the treated water flows by gravity from a covered storage tank. There were no known pressure failures at any point in the distribution system immediately preceding or during the outbreak. Plumbing in the school is comparatively new and is free of cross-connections. Daily bacteriological examinations of water samples collected from the distribution system near the school during April were negative.

On these facts alone, the water supply probably could be ruled out as a possible source of infection. Further evidence to remove the water supply from suspicion arises from the fact that several laboratories, classroom buildings,

and the infirmary in the university proper are served from the same source, yet the outbreak was limited to this one school.

All milk used in the dining hall is pasteurized. Unlike any of the 12 other dining halls, this one is furnished "bulk" milk in 10 quart containers delivered daily. The supplies are otherwise the same. Careful study of the handling of this "bulk" milk revealed no serious shortcomings in technic. Thorough and practically continuous refrigeration of the milk is stressed. Samples of the university milk supply are examined frequently, and the record during the period April 9-18 was good (Table 2).

There is further evidence that the primary source of milk supply was not the vehicle of infection. Part of the milk supply for a local hospital is delivered in 10 quart cans from the same pasteurizer runs as for the school. The cans used are interchangeable and not specifically earmarked for either place. There was no concomitant outbreak of gastroenteritis among the hospital personnel drinking "bulk" milk.

The Possibility of Infection by Food Handlers—Clearly, the source of infection must have been a local one; and presumably connected with the handling of food or utensils. General conditions of cleanliness did not favor the possibility that rats or other vermin

could have played a rôle. Contact was not considered to be a likely means of spread primarily because the outbreak involved the gastrointestinal tract and there was no known respiratory disease in this population group at the time of the present outbreak or after it had subsided. Furthermore, the sharpness of the epidemic curve ruled out contact infection as a major factor.

We next, therefore, turned our attention to the problem of the "carrier in the kitchen."

Copies of the menus for all meals served in the 13 dining halls in the university are kept on file and are currently reviewed by one of us. In this instance attention was focused on two meals at which potentially hazardous foodstuffs (cream puffs and chicken salad) were served in the dining hall used by those who had been ill. It was soon evident that some of the patients had not been present at one or the other of these meals, and data subsequently obtained from the questionnaires definitely eliminated each of these meals as the sole focus of infection. Of the group sick at any time during the epidemic there was no single meal at which all ate together.

At the outset of our investigation, it appeared that none of the 11 full-time food handlers had recently been ill. Also, no one of the students employed

part-time in the pantry or dining room was known to be ill. Certainly none had been sick enough to stop working. However, by the end of the outbreak 3 student employees were discovered to have suffered from the prevailing infection. Two of these cases had their onset rather late in the outbreak (on April 14 and 16). The third of these employees, however, was the second case revealed in chronological order, credited in Table 1 to April 11. We shall return to this case in a later paragraph; but he did not handle any food served in the refectory.

During the flare-up, no attempt was made to obtain stool specimens from other than one itinerant employee. Our previous experience with bacteriological studies of similar outbreaks had been discouragingly futile. Dack¹ confirms our belief that there can be no substitute for painstaking epidemiological study in attempting to find the source of a presumably food-borne outbreak.

In this instance the start of our investigation was comparatively late, patients were but mildly ill, and we had no early evidence of the magnitude of the outbreak. In retrospect, our study would have been more comprehensive had we had laboratory help, and we cannot be sure that there would not have been significant findings from a thorough bacteriological work-up.

The Possibility of Infection by Dishwashers—It was intensive study of the earliest cases in the outbreak which ultimately opened up a reasonable explanation. It will be noted that Table 1 contains one entry for April 10. This student (X) became ill at 10 a.m. on that day, the morning that school reopened. He doubtless was infected elsewhere. He had nausea, chills, and "high fever," and was bedridden 3 days in his room.

Although X was not a dining hall employee, he roomed next to Y, the second person ill in the outbreak (the student

dining hall employee noted above). Y did not handle food, however, but was responsible for drying dishes and silverware after they were taken from the dishwashing machine at the morning and noon meals. He was nauseated from the morning of April 11 through the 14th, but never vomited and had no diarrhea. He was not bedridden, and did not leave his job.

There were no additional cases until late evening of April 11.

In the absence of any tangible evidence to demonstrate another source and mode of spread, it is suggested that Y is the probable source, and that contaminated dishes or silverware served as vehicles for the spread of the infection.

Further credence may be given to this theory inasmuch as the 11 full-time employees previously mentioned (none of whom was ill) eat the same food-stuffs that are served students, *but the employees' eating utensils are washed, dried and stored separately from those used by students. Y did not handle the employees' utensils.*

Dishwashing Procedure—A mechanical double-tank dishwater is used in this dining hall. There are indicating thermometers on both the wash and rinse water lines, and usual water temperatures at these stages are 142° F. and 170° F., respectively. At the time of our initial investigation of this outbreak the rinse water temperature was 165° F., and trays passed through the conveyor-type machine in 25 seconds. The dining hall supervisor stated that trouble had been encountered recently in keeping the wash water below 145° F., and that frequent adjustment with cold water was necessary. Because of the valve arrangement, the rinse water temperature was lowered simultaneously, but not below 160° F.

It has been the practice to "towel-dry" all eating utensils in the dining halls, primarily because glasses and

dishes otherwise are spotted or streaked. Even though we do not approve this practice, it is our opinion that the methods used are satisfactory. An ample supply of clean, well laundered towels is provided at each meal. Bacteriological analysis of swab samples taken from utensils before and after towelling have revealed no significant changes in counts, and in any event the number of colonies found has been far below the usual standard of 100 per utensil.

In retrospect, a noteworthy fact was recorded at the time of our first inspection on the morning of April 14: A relatively large number of "clean" dishes, stored in warming cabinets, had adherent cooked food particles, principally egg yolk and jam. No particular attention was paid to this finding at the time except to have all dishes rewashed.

All dishes in regular use are stored between meals in uninsulated but bright-walled warming cabinets, heated from steam coils. Steam pressure of approximately 16 lbs. per sq. in. is maintained between 6 a.m. and 10 p.m., and with the cabinets closed the air temperature approximates 150° F.

Previous tests have shown that utensils in closed warming cabinets are subject to bactericidal action, and that counts on such utensils drop approximately 90 per cent when stored 4 hours. However, we were able to demonstrate

that a 24 hour broth culture of *Staphylococcus aureus*, when smeared in thin film on a clean, sterile Petri plate, proliferated after 7 hours in a closed warming cabinet of which the air temperature was constantly in the range 149°–158° F. (65°–70° C.). Similar tests made simultaneously with *Salmonella enteritidis* and *Micrococcus caseolyticus* were negative.

In practice, the doors of warming cabinets are frequently left ajar, and occasionally wide open. Although no temperature readings were made in the warming cabinets at the time of the epidemic investigation, dishes could be handled easily, indicating that the temperature was probably well below 150° F.

SUMMARY

An outbreak of 64 cases of acute gastroenteritis of unknown etiology has been described. After sifting all available evidence, it is concluded that the disease was spread by contaminated eating utensils. Data to support this theory are presented.

ACKNOWLEDGMENT — We are grateful to Professor C.-E. A. Winslow and Miss Margaret A. Bowers for their helpful advice and assistance.

THAT the incidence of staphylococcus intoxication must be considered as one of the ranking problems facing public health workers interested in food sanitation is evidenced by the rapidly increasing number of confirmed cases reported. Much difficulty has been encountered in the laboratory in attempting to elucidate and to harmonize the many facets which the problem presents. This is a report on a study of one of the more practical aspects of the staphylococcus food intoxication problem: an attempt to establish thermal death time-temperature relationships for one strain of staphylococcus in cream filling and to correlate the results thus obtained with the temperatures attained in accepted cooking procedures for cream filling. Bacteriological examination was made of cream filling subsequent to placing it in cream puff pastries. It appeared that information of such a nature might be of some help to public health officials who were interested in the requirements for cooking cream

fillings, the re-heating of pastries as a means of protecting the public against illness due to the ingestion of staphylococcus in cream filled products, and the part played by the food handler in the contamination of such products.

The effect of cooking procedures on the survival of staphylococci has been investigated in other laboratories. In 1931 Dack, Woolpert, Noble, and Halliday¹ observed that staphylococci introduced into either sponge or butter cake batter were killed during the baking process. All viable cells seemed to be destroyed when the interior temperature of the sponge cake batter reached 75.2°C. Staphylococci introduced into cream filling were said by these authors to be destroyed during cooking, but no detailed data on this point were presented. Coughlin and Johnson² without presenting experimental evidence suggested that in order to prepare custard mix (cream filling) safely it should be heated to not less than 200°F. for 10 minutes, and then cooled promptly. Cathcart, Merz, and Ryberg³ reported that cell suspensions of *Staphylococcus aureus* inoculated into the "thickening mix" of custard (cream filling) were destroyed by bringing the product to the boil. Internal temperatures of the cream fillings were not reported by these

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-Fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

authors, but were apparently assumed by them to be at or near the boiling point of water.

The rebaking procedures for cream filled pastries suggested by Stritar, Dack, and Jungewaelter⁴ to insure greater safety to the consumer necessarily required investigation of rate of heat penetration into such products. They recommended the routine use of ovens heated from 190.6°C. to 218.3°C. for 30 minutes. Cells of staphylococci inoculated into the cream filling were found to be destroyed by such treatment. Maximum temperatures for the cream filling within the pastry of 75°C. for 5 minutes and of 76.7°C. for 6 to 8 minutes were recorded for uncovered and covered pans, respectively. Gilcreas and Coleman⁵ reported somewhat similar data. Using inoculated custard (cream filling), the latter workers observed that no viable staphylococci cells were demonstrable following rebaking of eclairs. They determined that by such a procedure a maximum temperature of 71°C. was found to exist in the cream filling for a period of more than 5 minutes.

The investigations of Hucker and Haynes,⁶ Nunheimer and Fabian,⁷ and of Ryberg and Cathcart,⁸ which indicate that temperature necessary to free a mixture of ingredients of staphylococci is related to the composition thereof, cannot be ignored.

MATERIALS AND METHODS

A. Preparation and bacteriological examination of cream filling:

The formula and procedures used for the cream filling were as follows:

Flour	80 gm.
Sugar	200 gm.
Salt	6 gm.
Milk, reconstituted evaporated	980 ml.
Eggs	200 gm.
Vanilla	6 ml

The sugar, flour, and salt were mixed

and then made into a paste with 100 ml. of the milk. The remainder of the milk was placed in the top of a 1½ quart double boiler, and a copper-constantin thermocouple attached to an automatically recording six-point recorder* was inserted into it. The milk was heated until it foamed and then it was poured with stirring into the sugar, flour, salt, and cold milk mixture. During this time of mixing and for all others, measurement of temperature was discontinued and was reinitiated when the mixture was returned to the stove for further cooking. The milk containing the thickening mixture was heated in the upper part of the double boiler over 1 liter of boiling water for 8 minutes, by which time it had attained maximum thickness. It was then covered with a tightly fitting lid, perforated in such manner that a thermocouple was permitted to pass through. Heating was continued for 15 minutes, the mixture being uncovered and stirred at 5 minute intervals. The hot mixture was then added to the eggs with stirring. The water in the lower part of the double boiler was adjusted to 90°C., and the cream filling was heated in the upper part of the double boiler for another 5 minutes. At the conclusion of this cooking, the whole was beaten for 30 seconds with the electric mixer† at medium speed in order to assure uniformity and to hasten cooling. The cream filling was then poured into two cream soup plates and placed in a refrigerator which registered 4°C. for 30 minutes. Hydrogen ion determinations were made on the filling using a potentiometer.‡ Seventy gm. of the cream filling were weighed into each of eight previously prepared cream puff pastries.

Adequate supplies of all staples and

‡ Leeds and Northrup, Philadelphia, Pa.

milk for use throughout these experiments were obtained before beginning work. The eggs, produced by the university flock, were purchased as needed, two dozen at a time. The laboratory worker washed her hands in mercuric chloride solution, then in soap and water, and dried them on a sterile towel previous to beginning cookery each day. Frequent washing of the hands in soap and water was practised throughout the ensuing time of work. A face mask, covering nose and mouth was worn during all manipulative procedures.

The cream puff pastries which were prepared in the laboratory were handled with wax paper. The tops of the pastries were cut off, the cream filling was inserted, and the tops replaced. The filled cream puffs were wrapped in a wax paper and stored in four different ways: two were quick-frozen immediately, two were placed in a household refrigerator, two were held at room temperature, and two were placed in a 37°C. incubator. At the end of 24 hours and again at the end of 48 hours, a small amount of filling and a small amount of pastry from one cream puff representing each method of holding were each placed in 10 ml. of sterile water and shaken thoroughly. Phenol red mannitol agar and bromthymol blue lactose agar pour-plates were inoculated with these suspensions. Eight baking trials were made, and from these 256 platings.

Any colonies appearing on the plates were transferred to nutrient agar slants, incubated at 37°C. and the growth thus obtained was studied microscopically, using the Gram stain.

B. Thermal death time determinations:

1. Preparation of sterile cream fillings—A cream filling was prepared by the method described above except for the following alterations in ingredients and procedures: (1) All equipment to be used including bowls, spoons, knives, double boiler and lids were sterilized in

the autoclave. Ingredients were weighed into these sterile containers and were immediately covered with the paper which had been in place during sterilization. Mixing in so far as possible was done under these papers or sterile lids.

(2) Specially treated flour and sugar* were obtained. In our laboratory these ingredients were sterile on all test platings on tryptone glucose extract agar.† (3) No thermocouple recordings were made during the heating. (4) After thickening following the addition of the flour and sugar to the milk, the mixture in the upper part of the double boiler was placed over the direct flame and brought to a vigorous rolling boil for 5 minutes and then returned to over-water cooking, and allowed to cool sufficiently so that it could be added to the eggs. (5) At the conclusion of cookery the filling was poured immediately into four weighed, sterile metal cups, which were attachable to an electric blender. Approximately the same quantity of filling was placed in each cup. The cup was opened as briefly as possible and as soon as the filling was placed therein, and the cover returned, the whole was placed in a refrigerator. The pH value of each batch of cream filling prepared was determined electrically.

2. Preparation of the inoculum—Twenty-four hour growth of *Staphylococcus aureus* Strain C12069 (Dolman) from 2 large tryptose agar slants‡ was suspended in 10 ml. of sterile saline. The saline suspension from both slants was poured into a 200 ml. Erlenmeyer flask which contained 40 ml. of sterile saline and glass beads, and was shaken. The suspension was diluted until, using matched tubes, a reading of 40 per cent light transference was obtained on a photoelectric turbidimeter, using a

* The Griffith Company, Chicago, Ill.

† *The Difco Manual*, Difco Laboratories, 7th Edition, p. 23

‡ *Ibid*, p. 90

yellow-green filter, number 530.* Preliminary tests had shown that such a reading was approximately equivalent to 100,000,000 cells per ml. of suspension.

3. Preparation of thermal death time tubes, heating and plating—Aliquots of the cream filling for use as control experiments were withdrawn from the cans and manipulated in the same manner as the inoculated samples.

A sufficient quantity of the suspension of cells of *Staphylococcus aureus* Strain C12069 described above was added to the cream filling remaining in the metal cup to give a calculated inoculum of 100,000,000 cells per gm. The inoculum was incorporated by beating for 3 minutes with the electric blender.† Platings of 1 ml. of this inoculated filling in 1:1,000,000 dilution were made on tryptone glucose extract agar. The average of the plate counts for all such platings made (47) served as a measure of the number of cells in the unheated filling.

One ml. portions of the inoculated cream filling were put into thermal death time tubes of the type described by Sognefest and Benjamin,⁹ using a standard sterile 10 ml. syringe and a 12 gauge, 5 in. needle. The tubes upon receiving the 1 ml. of inoculated filling were covered with cotton until sealed. Triplicate tubes were used at all temperatures and at all time intervals in each experiment. In all cases at least 3 complete experiments, and thus 9 tubes, were used. This is essentially the technique first proposed by Bigelow and Esty.¹⁰

After sealing, the tubes containing the inoculated filling were heated in a DeKhotinsky constant temperature oil bath‡ for varying lengths of time. The temperature of the oil bath was con-

trolled by means of a thermo-regulator, and the heat was kept uniformly distributed throughout the bath by an electrically operated stirring device. At 55°C. the time intervals of heating were 4, 5, 6, 7, 8, 10, 12, and 30 minutes; at 65 and 75°C. the time intervals were the same except that the 30 minute observation was omitted. At 85°C. 2, 3, 4, 5, and 6 minutes were the intervals employed.

Upon the completion of heating, the tubes were iced instantaneously. Removing the filling from the tubes was accomplished by adding 1 ml. of sterile saline to the filling in the tube and mixing with a sterile, cotton-plugged, capillary pipette. After a uniform mixture was obtained, a measured quantity was placed in a test tube containing a sterile saline dilution blank.

It was necessary for the final dilutions of the inoculated filling to vary with the time and degree of heating in order to secure plates which were suitable for counting. The dilutions which were found to be applicable in this series of experiments are indicated below.

55°C.—all time intervals—1:400,000

66°C.—all time intervals—1:2,000

75°C.—all time intervals—1:200

85°C.—all time intervals—1:200

In all cases 0.1 ml. of the dilution shown above was plated. The platings were made on tryptone glucose extract agar. The counts were recorded and the per cent of survivors calculated.

As a basis for comparison the thermal death time temperature relationships of the same strain of *Staphylococcus aureus* in a pH 7.0 phosphate buffer was determined in a similar manner. One ml. portions of suspension of viable staphylococci cells standardized as to approximate number by use of the photo-electric turbidimeter placed in thermal death time tubes. These tubes were sealed and heated in the constant temperature oil bath. The temperatures and times used

in this series were: 4, 5, 6, 7, 8, 10, 12, and 30 minutes at 45 and 55°C. and 4, 5, 6, 7, 8, 10, and 12 minutes at 65 and 75°C., respectively. After heating, dilutions were made as follows:

- 45°C.—all time intervals—1:10,000
- 55°C.—all time intervals—1:1,000
- 65°C.—all time intervals—1:100
- 75°C.—all time intervals—1:100

One-tenth ml. of the final dilution as indicated was plated on tryptone glucose extract agar, and counts were made and recorded. These counts were compared with the average number of cells known in approximation to have been present in the unheated phosphate buffer suspension, by counts of 46 platings. Percentages of survivors were calculated.

The time which was required for the temperature of the contents of the tube to reach the temperature of the oil bath (lag time) was determined for both the cream filling and the phosphate buffer, using a specially constructed copper and constantin thermocouple* and a potentiometer indicator.† Time in

seconds for this lag was noted using a stop watch and was recorded.

RESULTS AND DISCUSSION

In Table 1 are presented the results obtained in the thermal death time determination for *Staphylococcus aureus* Strain C12069 (Dolman) in cream filling. It can be seen that small numbers of this organism (8.2 per cent) seemed to survive heating for more than 30 minutes at 55°C. Furthermore, with the cream filling as the suspending medium, this strain of *Staphylococcus aureus* apparently was killed by 8 minutes of heating at 65°C., less than 4 minutes of heating at 75°C., and less than 3 minutes of heating at 85°C. The average pH value for the cream filling was 6.48. A consideration of the time lag in the penetration of the heat into the cream filling in the tube must be made, however, before these values for time-temperature relationships in destruction of the organism can be accepted as absolute. The lag times in heating at 55, 65, 75, and 85°C. were respectively: 2 minutes 10.0 seconds; 2 minutes 22.1 seconds; 2 minutes 28.3 seconds; and 2 minutes 31.0 seconds. At all temperatures there was a substantial length of time before the cream filling within the

* Furnished through the courtesy of Dr. J. M. Jackson, American Can Company, Maywood, Ill.
† Number 522169, Leeds and Northrup, Philadelphia, Pa.

tube reached the temperature being tested for its lethal effect upon the cells. It is probable, therefore, that viable cells were destroyed in somewhat less time than is indicated for each temperature in Table 1.

For all of the control experiments using sterile cream filling and the techniques described, the results were negative. No colonies appeared on the tryptone dextrose extract agar plates even though the tubes of cream filling were heated for only the shortest time interval under test.

The results obtained when a phosphate buffer with a pH value of 7, was used as a suspending medium for viable cells of *Staphylococcus aureus* Strain C12069 (Dolman) are shown in Table 2. Sterilization was apparently effected at a lower temperature under this condition. Growth on tryptone dextrose agar later was obtained from the suspension of cells heated 30 minutes at 45°C. This was also true to a slight degree for cells heated up to 7 minutes at 55°C. However, beyond that point and at all time intervals tested at 65°C. and 75°C., the viable cells apparently were killed. Uninoculated phosphate buffer, manipulated in the same manner as the cell suspensions appeared to be sterile. As might have been expected, lag in time of heating the tube contents to the temperature of the oil bath was less for phosphate buffer than for the

cream filling. These lag times were determined to be 44.2 seconds, 54.6 seconds, 1 minute 37.2 seconds, and 1 minute 51.8 seconds, at 45°, 55°, 65°, and 75°C., respectively.

It would appear that during the preparation of the filling, the milk, flour, and sugar were maintained at a temperature of above 65°C. for much longer than the 8 minutes apparently necessary for sterilization of staphylococci. Following the addition of the eggs, the temperature appeared to remain above 75°C. for a sufficient length of time to free the mixture from staphylococci.

These findings were further verified when cream fillings were plated, which were carefully prepared from ingredients purchased in ordinary retail markets, placed in cream puff pastries, and held under varying conditions. Growth appeared on 92 of 256 plates but staphylococci were never detected. For the most part the organisms recovered appeared to be large spore-bearing rods and occasionally *Sarcina*. Staphylococci could have been overgrown on many plates in this series but on the whole, with the temperatures known to have been applied during cookery and a knowledge of the thermal death relationships of the organism in cream filling, it appeared that this filling was sterile for staphylococci when cooking was completed.

In the thermal death time trials at 55°C. the increase of cells above 100

per cent of the inoculum may require comment. It seemed possible that the very length of the manipulation may have been explanatory. However, a series of experiments in which the cream filling was held in ice from the point of inoculation and except for the heating period to the moment of plating, seemed not to eliminate the phenomenon. It may have been that certain of the procedures used succeeded in breaking up cell clumps. At the longer heating periods, cell metabolism may have been driven to a higher pitch and thus cell multiplication occurred more rapidly.

The method used here for mixing and cooking cream filling differed in some details from the method described by Stritar, Dack, and Jungewaelter⁴ and Cathcart, Merz, and Ryberg.³ The variance occurs chiefly in degree of heat applied. At no point in the techniques here reported was the mixture boiled. This method is in harmony with the recommendation of many authoritative quantity cookery recipe books and is based upon the usual principles for proper starch and egg cookery.

The thermal death temperature-time relationships determined here may perhaps be applicable to the feasibility of rebaking cream filled mixtures as a public health prophylactic measure. When the temperatures attained in the rebaking procedures developed by Stritar, Dack, and Jungewaelter⁴ were compared with critical thermal death times and temperatures as observed here, it appeared that their method allowed for reaching the minimum or in excess of the minimum for destruction of staphylococci, when the cream puffs were maintained in an oven of 190.6°C. for 30 minutes. The technique for rebaking of cream filled mixtures as described by Gilcreas and Coleman⁵ allowed little, if any, margin of safety in time and temperature necessary to destroy organisms, when considered in light of the results presented

here. Apparently there is some merit in the rebaking procedures but it would appear that bakers must be cautioned to control the conditions carefully under which the work is done, or a false sense of security may result.

SUMMARY AND CONCLUSION

Using the multiple tube method, an attempt was made to establish thermal death time-temperature relationships for staphylococci in cream filling and to correlate such findings with the range and duration of temperatures attained in accepted cooking procedures for cream filling. One strain of *Staphylococcus aureus* was used as the test organism. Thermal death time determinations for the same organisms were also made at a range of temperatures, using a pH 7 phosphate buffer solution for the suspending medium.

In the range of temperatures studied, *Staphylococcus aureus* Strain C12069 (Dolman) was found apparently to survive for 30 minutes at 55°C. and to be destroyed in less than 3 minutes of heating at 85°C. In phosphate buffer solution, pH 7, the organism survived somewhat less stringent heat treatment. It appeared that at the conclusion of such a cooking procedure, cream filling was free from viable staphylococcus.

Haven Emerson to Deliver Cutter Lecture

The Harvard School of Public Health announces that Dr. Haven Emerson, Emeritus Professor of Public Health Practice, Columbia University School of Public Health, New York, will deliver the Cutter Lecture on Preventive Medicine on November 24, 1947, at 5 p.m. in Amphitheatre D of the Harvard Medical School. Dr. Emerson has chosen as his subject, "Whither the

Pegasus of Public Health?" The Cutter Lectures on Preventive Medicine have been held since 1912, according to the terms of the will of Dr. John Clarence Cutter, of the class of 1877, which directed that they should be "free to the medical profession and to the press." In addition, medical and public health students and others interested are cordially invited to attend.

Canada Sees New Horizons for Health Education*

LT.-COL. C. W. GILCHRIST, O.B.E., E.D.

Director of Information Services, Department of National Health and Welfare, Ottawa, Canada

IN order fully to appreciate the scope and progress of health education work north of the 49th parallel, one must first have a quick glimpse of the geography, the economy, and the governmental set-up of Canada.

Here is a vast country, with lines of communication covering more than three million square miles, whose population of twelve and a half million is concentrated in a "strip" along the southern border. Here is a nation which in a quarter century has twice marched to war and in eleven years of all-out effort contributed men, money, machines. Here is a nation now risen from comparative obscurity in world affairs to a secondary power, third only to the United States and Great Britain as a trading nation.

With a central federal authority and nine autonomous provincial governments, Canada has its problems of administration. There are the "have" and "have-not" areas. There are the two official languages.

But certainly in the twin fields of health and welfare there is very close federal-provincial coöperation. It has developed over the years, despite the fact that the British North America Act of 1867, Canada's Constitution, only very sketchily laid down the responsibilities of governments at the two levels.

The Dominion had certain statutory obligations—among them, administration of the Food and Drugs Act, the Quarantine Act, The Opium and Narcotic Drugs Act. Responsibilities were divided among several departments, but in the broad field of public health education comparatively little was accomplished on the federal level until 1944 when Parliament passed "An Act To Establish a Department of National Health and Welfare." It was to take over the health function of the Department of Pensions and National Health.

One of the most important provisions of the new act was this: "Coöperation with provincial authorities with a view to the coördination of efforts made or proposed for preserving and improving the public health and providing for the social security and welfare of the people of Canada."

It was early seen that one of the most effective measures of coöperation would be that of health education. The provinces, active in varying degrees in such fields as child and maternal health, nutrition, mental health, blindness control, industrial health, dental health, venereal disease control, welcomed the emergence of such new divisions at the federal level. Busy with the organization of local health units and other administrative detail, provincial authorities were pleased to take advantage of consultative services and health education materials made available to them free of charge.

* Presented before the Public Health Education Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 10, 1947.

In November, 1946, the first Dominion-Provincial Health Education Conference was held. Such a conference had been recommended by the Dominion Council of Health, which has often been referred to, somewhat erroneously, as "Canada's Health Parliament." The Council is composed of the chief executive officer of the provincial department or Board of Health of each province, representatives from the fields of science, agriculture, labor, and English and French-speaking women's organizations. Twice yearly for three days the Council meets in Ottawa under the chairmanship of the Deputy Minister of National Health and, while it is not empowered to make regulations, its recommendations to the Minister have resulted in many health improvement measures of far-reaching significance.

This year health educators and others in the field will be called together again as guests of the Department of National Health and Welfare. Under review will be the first full year of coöperative effort toward improvement in quality and output of health education materials at all levels. Continuing to provide leadership in the production of books and pamphlets, radio material, posters, displays and films, the federal department has also acted as a clearing house for ideas and materials produced by provincial authorities, thus insuring that all parts of the country are kept acquainted with progress elsewhere.

Health educators of the government services and those with voluntary agencies are unanimous in their opinion regarding the teaching value of the motion picture. The Department of National Health and Welfare has during the last year or two devoted a sizable slice of its education and information budget to this medium. Not only have we produced 17 films and filmstrips of varying length, with 13 more in production or in the scripting stage, but we

have built up in conjunction with the National Film Board, four one-print film libraries. There are a Public Health Library with 150 titles, a Biological and Medical Library for professional use with a like number of prints, a Physical Fitness and Recreation Film Library, and a Welfare Library, the latter newly organized.

All the best material from Canada, the United States, Britain, and many other countries is screened and evaluated by professional and lay committees, and prints are made available to government departments, organizations, or individuals on a low-cost rental basis.

The National Film Board, a government agency, is responsible for all original productions, and I should like to call attention to the fact that several of our Canadian films are being shown daily in Mr. Stowell's "little theatre."

New productions include the following "Mother and Her Child," "Let's Look at Water," "Your Morning Milk," "Know Your Baby," "Condition Improved" (occupational therapy); "Rural Health," "Small Fry" (pointing up the contribution of Family Allowances to the welfare of Canada's children); "Sixteen to Twenty-Six" and "Very Dangerous" (adapted from R.C.A.F. venereal disease films for female and male audiences respectively); "What's on your Mind" (mental health); "Stanley Takes a Trip" (a color cartoon film on nutrition), and "The Feeling of Rejection."

The last mentioned is the first in a proposed series entitled "Mental Mechanisms" designed to illustrate the development of personality factors which often lead to emotional difficulties and physical distress. It is, we believe, a valuable tool in group psycho-therapy and is useful for parent-teacher education and in the instruction of social workers, nurses, and medical students.

Then, scheduled for release is a film on "Hostility," the second in the

Mental Mechanisms series; two short films on Rural Sanitation and Rat Control; a two-reeler on Immunization, stressing parental and community responsibility; a color film on Dental Health; a color filmstrip and a black-and-white film for professional use on Narcotic Drugs; a brief film called "Fit for Tomorrow" on community recreation programs; a film on Restaurant Sanitation; a series of six cartoon filmstrips under the title "Why We Eat" and another filmstrip, called "Internal Triangle" showing the adaption of Canada's Food Rules to meal planning.

The first-named film—"Mother and Her Child"—which is in color and synchronized sound and 50 minutes long, is based on the book *The Canadian Mother and Child*, written by Dr. Ernest Couture, director of our Division of Child and Maternal Health. More than 800,000 copies of the 232 page book have been distributed free in the last few years and we are now going into the seventh reprint. In addition to the film we have produced two complementary filmstrips on prenatal and postnatal care—"Nine to Get Ready" and "Introducing Baby." Films are produced in both English and French.

In printed materials the aim always is toward attractive format, bright design, interest, readability. We believe the health story can be told effectively in everyday language. Scientific gobbledy-gook is out. Old publications are constantly under revision and new ones planned.

The success of this policy may be indicated by the fact that last year we published and distributed free to the provinces and to organizations and individuals more than two million pieces of printed material. New Zealand has recently requested permission to reprint one of our booklets. Tasmania is interested in another.

One publishing project planned is a series of three companion pieces to *The*

Canadian Mother and Child. They will cover the growth and development of the child from one to six, the school-age child and the adolescent. Another afoot is a series of four booklets under the general title "Posture's Important."

All publications, including posters, are produced in English and French editions. This includes three monthly periodicals—*Canadian Nutrition Notes*, *Industrial Health Bulletin* and *Canada's Health and Welfare*. The last is the departmental magazine; with a circulation of 85,000, it serves as an informational liaison link between all branches of government down to the municipal level and voluntary organizations.

As an example, the magazine is now carrying a series of illustrated supplements on specific health subjects. The first of these was on cancer and 450,000 copies were made available to the Canadian Cancer Society for distribution.

The federal department, indeed, co-operates closely with all national voluntary health and welfare organizations. Newsclips and exhibits have been provided free to the Health League of Canada, and the film on immunization mentioned above, is being made to tie in with the League's national immunization campaign. The Canadian Welfare Council formerly produced quantities of literature on child care and training for sale near cost. These publications have now been taken over by the federal department, being revised and reissued free through Information Services Division.

More recent additions to the Health Branch of the department—new Divisions of Hospital Design, Civil Aviation Medicine, Health Insurance Studies, Civil Service Health, Epidemiology—all pose special problems and bring new opportunities in the field of health education. For the first named, as an example, we have published a portfolio of plans of small hospitals and health

units which, like all our literature, goes free to provincial departments and municipalities.

There is a challenge, too, in the work of the Welfare Branch of the department which is responsible for the Old Age Pensions Act, the Physical Fitness Act, and administration of Family Allowances.

Canada is the only country of the Western Hemisphere with a system of family allowances. Every child in Canada—and there are now 3,704,622 registered—receives a monthly payment, ranging from \$5 to \$8, from the government. It is paid to the mothers from the time the child is born to 16 years of age. On an average month 22 million dollars goes out by cheque. In the two years and three months since Family Allowances came into being nearly 550 millions have been distributed, mostly among the wage earners in the lower brackets.

We know that Family Allowances have accomplished several things already. There has been an improvement in the dietary habits of the nation. Notably there has been an increase in the consumption of milk and milk products as well as fruits. There has been an improvement in school attendance, because that is one of the conditions of payment—and many children are now being properly clothed and equipped to go to school. The psychological effects are incalculable.

In two years there has yet to be a conviction for misuse of these allowances, but there is much to be done in an educational way to insure the *best* use. It is a task of the Information Services Division to help tell thousands of mothers about better money management.

Canada's Indians and Eskimos get Family Allowances, too. Some of them in remote areas are paid "in kind"—that is, receive the value of their cheques in goods from local trading posts.

Much is being done, more planned, to improve the health of Indians and Eskimos. Cooking courses and home-makers' classes are carried on. We have produced colorful calendars with simple health slogans to go out with Family Allowance cheques. Films are used extensively for teaching, and we are now producing literature in Cree and Eskimo syllabics as well as English and French.

I earlier mentioned radio as a medium. The Canadian Broadcasting Corporation has done a notable job in the health education field. Not only do we maintain a close liaison, but the CBC producers also work with other government departments and voluntary agencies in telling the story to the public. For the CBC and private radio stations in Canada we produce a regular service of broadcast material.

The press, as always, coöperates splendidly, and it is worthy of mention that more than one-half of the weekly newspapers in Canada, both English and French, publish a weekly column produced and issued by my division. In times of epidemic or emergency the daily newspapers and the radio stations can always be relied upon to flash the necessary warnings and instructions to the public.

I regret that there is not space to discuss in detail the health education programs in the provinces, five of which—British Columbia, Alberta, Saskatchewan, Manitoba and Quebec—have full-time health education divisions. May I leave with you, just a few highlights:

British Columbia points with pride to the fact that she leads all the western provinces in percentage of population covered by full-time health units as well as in number of health units. More than 65 per cent of the population is served by this modern type of health program. In addition, public health nursing service is available to nearly 90 per cent of the population. A consultant in health education, Miss Kay McNevin,

was added to the staff early last year. The Health Department and the Department of Education are planning and conducting experiments in venereal disease education in high schools.

Province of Alberta—One of the most notable experiments in the province was carried out in the Lamont Health District. As a publicity and teaching enterprise for the benefit of the housewives of the district, a six week camp for undernourished boys was conducted. The unusual nature of the camp, together with the general improvement in the health of the thirty boys who attended, aroused much interest, and the community was ready for and receptive to further nutrition education. Projects in community nutrition were expanded. These included the distribution of vitamins to preschool and school children, location and publicizing of local food sources with information on the best preparation of such foods, dietary surveys and general education implemented by lay participation, and nutrition education in the schools.

In *Saskatchewan* the Division of Health Education, headed by Christian Smith, has hitched its educational program to the family and it has consistently maintained a psychiatric approach to delinquency, venereal disease, alcoholism, and other subjects. Relating this to the changing school curriculum, the division has persuaded the Department of Education to introduce family life education in the secondary schools, starting in Grade 10 and developing this as a compulsory subject for both sexes in Grades 11 and 12 (senior matriculation). The Department of Education has also been persuaded to include human reproduction in physiology (starting at Grade 10) and the venereal diseases with communicable diseases in Grade 10 study.

In the realm of publicity and public relations, the division in two months "sold" the compulsory hospital services

insurance plan to the people of the province; helped to persuade 35,000 residents of a rural area to accept full-time public health services on a regional basis; conducted a successful recruiting campaign among high school graduates, university students, and teachers for mental hospital staffs.

Manitoba—Springboard of activities for the Division of Health and Welfare Education in Manitoba is the Health Services Act of 1945. Its four parts include the organization of health units, diagnostic services, prepaid medical care and hospitals. Various parts of the province are concerned with one or more phases of the plan and it is the responsibility of the Director, Miss Margaret Nix, once the details of the plan are complete, to go into the area and, with every educational and publicity means available, prepare the community to pass the necessary by-laws. In every case the votes have been favorable. Twelve health units which cover 45 per cent of the population have been organized, one diagnostic unit, four general hospitals, and twelve medical nursing units.

In *Quebec*, the Director of Health Education is a medical doctor, Jules Gilbert, who is also Assistant Director of the School of Hygiene, University of Montreal. The outstanding feature of his program has been the building up of a staff of public health educators of whom he now has 13 working in as many county health units with the adult population. These health educators are nurses with a pedagogical background and experience who have received additional training at United States universities. New health educators will be trained at the Montreal University School of Hygiene. In the field of school health, Quebec has sent 11 normal school teachers and school inspectors to take a full year's training in school health education at universities in the United States. Recently the

school health curriculum for elementary grades was revised, and to give impetus to this program a degree course in health education for teachers has this year been introduced at the Montreal University School of Hygiene with an initial enrollment of 40.

In *Ontario*, most populous of Canadian provinces, health education work is directed and correlated by Dr. D. S. Puffer, assistant to the chief medical officer of health. A notable recent development was an amendment to the Public Health Act providing for free medical examination of expectant mothers. Feeling that it was necessary not only to inform the public fully but to do an educational job on the doctors too, Dr. Puffer's office had 250,000 letters prepared and circulated outlining what it was hoped to accomplish by the new legislation.

The job was thorough. The regulation is applicable only within the boundaries of *Ontario*, but the health department finds doctors sending in reports on expectant mothers resident in *Manitoba*,

Quebec, and even the State of *New York*!

The Maritime Provinces of *New Brunswick*, *Nova Scotia*, and *Prince Edward Island* have taken notable strides since war's end setting up new public health services. The tools of health education available from the federal department are particularly useful to those provinces whose funds for development of their own materials are at a premium.

And so it is that the coöperative effort in Canada goes on. There have been many evidences of improvement in the health of the nation over the years. Further improvement is dependent largely upon informed and enlightened public opinion. Health education has many sides to it. It is a long-term investment. Together with other departments of government, with professional and lay groups, and with voluntary organizations, the Department of National Health and Welfare is at all times working to evolve practices which will raise the level of health and welfare of the whole Canadian people.

Administrative and Research Uses of Routine Analyses of Hospital Statistics*

PAUL M. DENSEN, D.Sc., F.A.P.H.A.

*Department of Preventive Medicine and Public Health, Vanderbilt University
School of Medicine, Nashville, Tenn.*

IN recent years, there has been a trend toward enlargement of the scope of statistical services in state and local health departments. To the traditional registration functions of the vital statistics office, more analytical functions have been added, sometimes directly within the vital statistics office; sometimes in some other division of the health department but still in close co-operation with the registration office.

This growth is the result of the recognition of the need for more factual data to aid in defining the nature and scope of the problems confronting the health department, to serve as the basis of intelligent planning for their solution and, finally, to furnish a means of evaluating the effectiveness of the attack on these problems.

In many hospitals, at the present time, there is a similar awareness of the need for quantitative analyses, both of problems within the hospital and of problems having to do with the relationship of the hospital to the community. In many instances, this awareness has crystallized in the development of a statistical unit within the hospital not unlike that which has com-

plemented the work of the registration office of the health department.

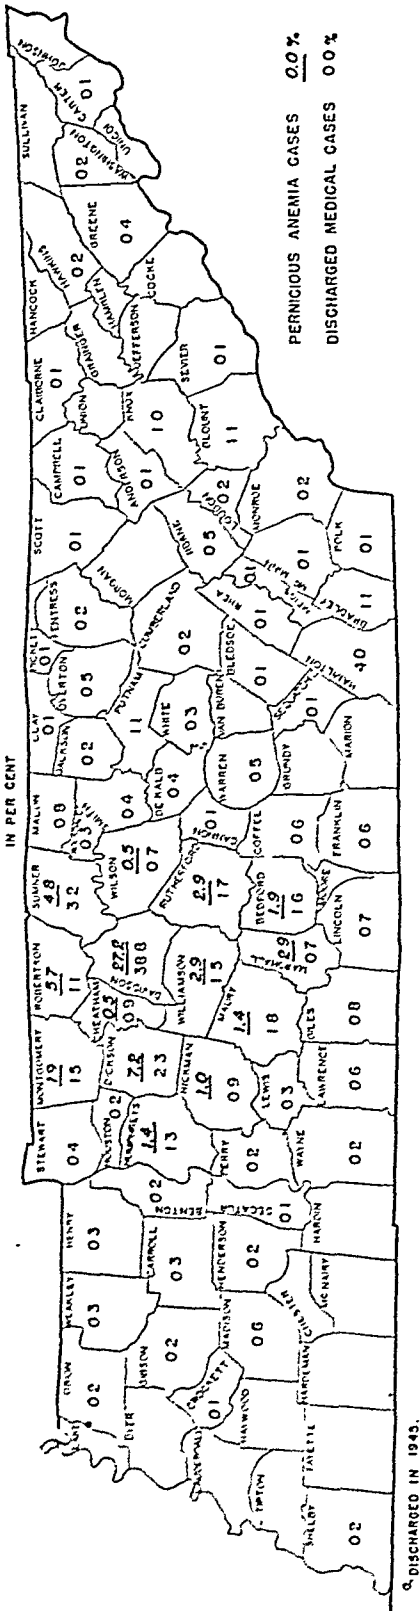

It is proposed here to present a few of the administrative and research uses of analyses of various types of hospital data. While the examples used reflect the experience of the Vanderbilt University Hospital, similar analyses are being made in many other hospitals. The examples have been chosen to emphasize a point; namely, that there is present, in the material accumulated in the hospital histories in the ordinary course of events, a wealth of information which, if tabulated and analyzed routinely, can point the way for more efficient hospital administration, indicate special problems needing study, and provide background data which may be used to great advantage in research problems.

ANALYSES OF DATA PERTAINING TO THE HOSPITAL AS A WHOLE

Every hospital history contains such basic facts as history number of the patient, his age, race, residence, and, in addition, certain data regarding his hospital experience such as length of stay, the service from which he was discharged, his status on discharge, and the final diagnosis. The general pay status may also be included, such as ward, low cost private, or private patient.

* Presented before the Vital Statistics Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

FIGURE 1
DISTRIBUTION BY RESIDENCE OF 1744 PATIENTS DISCHARGED FROM THE MEDICAL SERVICE^a
AND OF 309 PERNICIOUS ANEMIA CASES SEEN IN VANDERBILT HOSPITAL FROM 1925 TO 1945
IN PER CENT

From such information made available in easily tabulated form, as a punch card, a number of interesting administrative questions may be studied. For example, occupancy rates are usually available for the hospital as a whole but, like the crude death rate, the overall occupancy rate sometimes obscures situations revealed more clearly by specific rates. In a private hospital which relies for part of its income on the fees paid by private patients, the hospital administrator finds it useful to know the occupancy rate of the private service and of the ward service. Occupancy rates by department of the hospital are also very interesting. The rate of one department is not always comparable with that of another (e.g. obstetrics vs. medicine), but each department may be compared with itself over a period of time and the effect of changes in staff or of administrative policies on occupancy easily evaluated.

Many uses may be found for tabulations of the place of residence of the patients. In itself, it is desirable to know what area the hospital serves, especially if the hospital needs of the area are to be considered. Such data are also pertinent to any problem involving follow-up of patients, and they often prove of value from a research standpoint. For example, one of the clinicians noticed that the pernicious anemia cases seen in the hospital seemed to come from certain counties. The same observation had been made quite independently by another clinician and they wanted to know if there was any way to study the correctness of their impression quantitatively. It seemed reasonable to assume that if there was no geographic concentration of the cases, the distribution should not differ from that of other medical discharges. The number of pernicious anemia cases seen in a hospital like Vanderbilt over a period of time is not very great, so that the control series of discharges

would have to be fairly large if significant differences were to be demonstrated. To tabulate a sufficient number by hand would have been a rather laborious job but it was a simple matter to run the routine punch cards for the necessary data.* The results are shown in Figure I.

Study of Figure I confirms the impression of the clinicians. The differences seen in Robertson, Dickson, and Marshall Counties are greater than would be expected from chance alone. Moreover, the fact that the counties are not contiguous and that Davidson County, in which Vanderbilt Hospital is located, has a smaller proportion of cases than would be expected, suggests the hypothesis that the observed data are the result of a selective phenomenon

of some kind, possibly related to the concentration of physicians and their ability to diagnose pernicious anemia. Here, then, a simple tabulation from routinely collected data has answered a simple question which might otherwise have gone unanswered or have led to a laborious and expensive research project.

It may also be emphasized that the collection on punch cards of such routinely available data permits the accumulation of large numbers of observations which may serve as reliable controls for many hospital problems which of themselves yield only small study groups.

ANALYSES OF THE RECORDS OF
INDIVIDUAL DEPARTMENTS

In addition to the routine collection and analyses of data contained in the histories of all departments of the hospital, punch cards may be developed

* While the pernicious anemia cases were tabulated for the period 1925-1945, the data on all medical discharges were available on punch cards only for 1945.

FIGURE II

FETAL MORTALITY^a IN ALL DELIVERIES^b AND IN PREMATURE AND TERM DELIVERIES AT VANDERBILT HOSPITAL 1941-1945

by each department which will contain much more detailed but still routinely collected information than the card developed for the hospital as a whole. Some of the uses of such cards developed for individual departments follow.

Obstetrics Department:

Many administrative uses have been found for the data on the obstetrics punch cards. At the beginning of the war, the accelerated rise in the birth rate resulted in considerable crowding of the obstetrics facilities of the hospital, and the question arose as to how many more bed days would be made available if patients who had no complications were not permitted to remain in the hospital more than one week. It was a simple matter to sort out these cases, make the frequency distribution of length of stay in the hospital, and

observe the effect of reducing it to 7 days.

The statistics shown in Figure II on the fetal mortality among infants delivered in Vanderbilt Hospital have been used by the Pediatrics Department to indicate the need for a premature nursery. That they constitute a potent argument is self-evident.

From the research standpoint, the data collected on the same cards have proved of considerable value especially with respect to puerperal fever. In fact, the development of the punch card itself was enlightening for it became quickly apparent that the concepts of puerperal fever held by the obstetrics staff at the time were not very clear. Some included any temperature over 100°F. as puerperal fever; others used 100.4° as the dividing line. Some included the first 24 hours after delivery; others did not.

FIGURE III

PUERPERAL FEVER RATE BY PAY STATUS VANDERBILT HOSPITAL 1942-1946

Obviously a definition was needed. One was provided and the first tabulation with this definition was made in 1942. The results were surprising and are shown in Figure III.

Ward patients showed a puerperal fever rate in excess of 12 per cent, low cost private patients showed the next highest rate, and private patients had the lowest rate. The rate for ward patients seemed excessive and the rates were rising. Tincture of zephiran sprays were used by the obstetrics department in 1943 with no apparent effect. Vaginal instillations with an aqueous solution of zephiran were tried late in 1944 and early in 1945, still with no apparent effect. Then about April, 1945, the practice of issuing monthly reports on puerperal fever was adopted and the problem was kept constantly in front of the interne staff. They, in turn, posted a list in the nurses' station on the ward of all patients delivered and whether or not they developed puerperal fever. A noticeable spirit of rivalry developed and it came to be considered almost a disgrace for an interne to have one of his patients develop puerperal fever. It may be seen from the graph that the rate for 1945 was lower than for any of the three preceding years, and for the first 6 months of 1946 it has fallen to a new low and is now at the level of the rate for the low cost private patients. Since there had been no changes in obstetric practice during this time except for the exercise of greater caution in handling patients as a result of the constant awareness of the danger of puerperal infection, the drop in the rate appears to be due to the emphasis placed upon the problem.

As the data on puerperal fever were accumulated over several years, another advantage of routine tabulations of such data became apparent. The full study of the problem requires breakdowns along such lines as whether or not an operation was performed, whether there

was any relationship to the patient's hemoglobin level and packed cell volume, whether there were differences between primiparae and multiparae, etc. Breakdowns of this sort require a fairly large number of cases if the influence of the various factors is to be evaluated, but if the data are accumulated on punch cards, in time sufficient material becomes available so that they can easily be made. The labor involved in extracting the necessary data from the same number of cases all at one time is usually so great as to prohibit any attempt to make detailed analyses.

An important off-shoot of these routine analyses of the obstetrics records has been the Vanderbilt Coöperative Study of Maternal and Infant Nutrition. The impetus for this study arose out of discussions in 1944 of the apparent consistency of the differences in the puerperal fever rates among ward, low cost private patients, and private patients. Two possibilities were considered at the time: (1) that the differences might be due to differences in exposure resulting from different numbers of patients in a room in each of the three groups; (2) that the differences might be due to differences in nutritional status of the three classes of patients. Certain detailed tabulations suggested that the first hypothesis was probably not the sole explanation of the differential in the puerperal fever rate. Since the relation of nutrition to various aspects of pregnancy was of interest in itself, a detailed study of the subject was undertaken embracing several departments of the medical school. The relationship of puerperal fever to nutrition is just one aspect of the study, but it was the initial discussion of the results of the routine analyses that was the springboard for the development of this detailed research program.

The Syphilis Clinic:

The punch card for patients coming

FIGURE IV

PERCENT OF SYPHILIS CASES PROBATED PRIOR
TO 1941 FOLLOWED IN VANDERBILT HOSPITAL
CLINIC FOR SPECIFIED TIME PERIOD

to the syphilis clinic contains, in addition to identifying information, data with respect to diagnosis, treatment, results of serological tests, referral source, status at the time of disposal, and results of follow-up. Many analyses have been made of these data. The material in Figure IV illustrates one such analysis.

Patients who complete their treatment and who are placed on probation are asked to return each 6 month period up to one year and yearly thereafter. It is

seen from Figure IV, however, that between 30 and 40 per cent of these patients are lost to observation within 6 months, and considerably less than half are followed for as much as 2 years. Information of this type is of considerable significance with respect to the problem of evaluating the effectiveness of treatment. It is futile to seek such an evaluation in terms of the probability of a relapse within a stated period of time, for the condition of those

FIGURE V

CLINICAL AND LABORATORY FINDINGS IN A CASE OF TULAREMIA - PULMONARY
TYPE - SEEN IN VANDERBILT HOSPITAL 1938

who do not return to clinic is unknown and it may very likely differ considerably from the findings on those who do return. The analyses of the data routinely available in the records indicate that more effective means of following patients must be sought if evaluation in terms other than mortality is desired. Similar analyses can be made for any other clinic in which an attempt is made to have patients return for routine examinations.

The Hospital Laboratories:

Hospital laboratory records contain a wealth of data which if routinely analyzed and correlated with other records should do much to aid in the

understanding of the pathogenesis of disease and of the clinical significance of the laboratory findings. What is needed for such understanding is a continuity of observation which, unfortunately, is not present in the histories as often as it might be. For example, the director of the bacteriology and serology laboratories at Vanderbilt has made it a practice to bring together data in the histories of certain patients on whom laboratory procedures are requested. Figure V shows some of the data on a case of tularemia in which the laboratory was requested to run an agglutination test. One would like to know here what the course of the agglutination titer was as the clinical symptoms subsided. The

significance of the observed rise in titer cannot be fully appreciated without further observations. Routine bringing together of observations such as those in Figure V should eventually result in improvement in the records.

There is always a great temptation for the hospital staff to place considerable reliance upon a single laboratory report. If the report is positive, further observations may be desirable as shown in the example just cited. If it is negative, its significance may be still more obscure, depending as it does on such things as the way in which the specimen was collected, the accompanying clinical symptoms, and other factors. Attempts to evaluate such factors raise questions as to the information which the laboratory would like to have on the request for examination forms and as to the selection of patients on whom examinations are requested. Many of these questions can be studied by routine tabulation of the information present in the histories, and this in turn should result in the desired continuity of data.

Records of Hospital Employees:

Another source of information which lends itself well to routine analysis is the records of hospital employees. In many ways a hospital is like an industrial plant. It usually carries a sizeable number of people on its payroll, who are exposed to risks peculiar to the hospital environment just as workers in a steel mill are to their particular hazards. Industry has found that it pays in dollars and cents to maintain a health service and to keep records of industrial absenteeism. Relatively few hospitals, however, analyze their records in the same manner, yet all the necessary data are routinely available. The size of the employee population is known and the accounting office usually keeps a record of absences. If the hospital provides a health service for its employees, records are kept as to the causes of illness. All

that is needed to develop absenteeism data is organization of the already available records from the statistical point of view. Analyses of such data would not only be of administrative value but, if broken down as to type of hazard, would be of considerable research interest. For example, the absenteeism rate of laboratory workers might be compared with that of the housekeeping staff, just as the rate of workers in one department of a plant is compared with that of another.

GENERAL BENEFITS

Sufficient examples have been given to show that there are innumerable opportunities for analyses of the administrative and research aspects of hospital work. There are, moreover, certain general benefits not related to any particular department, which derive from the development of such analytical procedures in the hospital. As one department follows another in seeking to study the information routinely available in the records, a more critical attitude toward record keeping begins to develop. Records are looked at in terms of their potential statistical uses as well as their use with regard to the individual patient, and in the long run the records tend to improve.

The routine analysis of the records is also productive of much excellent teaching material. In a non-teaching hospital, such material as that cited above on puerperal fever results in an indirect form of staff instruction. In a teaching hospital, material on the prevalence of various conditions among the patients is of value in illustrating points in the courses in obstetrics, pediatrics, medicine, pathology, and others. If courses in medical statistics are given, laboratory problems can easily be constructed from the files of punch cards.

It is often found that analyses of the records point up problems which two or more departments of the hospital

may have in common, and fosters co-operative undertakings. A good example of this is the Coöperative Study of Maternal and Infant Nutrition previously mentioned. Then again, such analyses point the way for integration of preventive medicine practices with procedures in various clinics, as, for example, in indicating the need for x-raying all patients by examining the proportion of patients with a history of contact with tuberculosis.

But the development of routine punch card files is not only of value in correlating the work of one department with that of another; it should also be useful in correlating the records of the various hospitals in the community. As record forms and procedures are standardized, it should be possible to put together data for all the hospitals in the community to give a better idea of the hospital problem of the area. For example, if all the hospitals in Nashville routinely tabulated where their patients

came from, it would be possible to obtain a hospitalization rate for the city, inasmuch as only a very small proportion of residents are hospitalized outside the city.

Not only should routine punch card files aid in coördinating the records of the various hospitals in the community, but they should also prove useful in tying together the records of other agencies with those of the hospital. In many communities there is a woeful lack of coördination of the efforts of hospital clinic workers with those of other social agencies and with the public health agencies. The punch card files may present opportunities for identifying groups of individuals who may be found in the records of more than one agency, and this should do much to clarify some of the health problems of the community. In general, then, routine analyses of hospital records may be of benefit not only to the individual hospital but to the community as a whole.

Functions of Standing Orders for the Nurses in Industry*

IRVING R. TABERSHAW, M.D., AND
MARGARET S. HARGREAVES, R.N.

Liberty Mutual Insurance Company, New York, N. Y.

A **STANDING** order may be defined as an order for some form of treatment, medication, or procedure to be carried out by a nurse in the absence of a doctor. To be valid, it must be written, signed by a doctor, and applicable to a specific patient or situation. Such orders are of particular value in a hospital where they provide for standardized procedure, expedite care and treatment of patients in the temporary absence of the doctor. If carefully examined, standing orders in recognized hospitals will be found to consist only of the usual techniques which a nurse is qualified to perform in those situations which require neither diagnosis nor prescription. Patients admitted to a hospital are usually seen by a physician before or upon admission. The standing orders of a staff doctor therefore, merely serve as a guide for nursing routine to be carried out in his absence on patients whose condition he has diagnosed. They define what the nurse is permitted to do with the doctor's approval in his absence.

The problem of standing orders for nurses who see patients before a doctor is available for diagnosis and prescription is different. Visiting nurses are frequently called upon to give care in a

home before a physician arrives, and usually have standing orders to cover such situations. These orders are commonly formulated by a local public health agency and are very limited. They frequently do not even permit a visiting nurse to execute without a doctor's order, a procedure which could be classified as an ordinary home remedy. For instance, except in unusual cases such as a child in convulsion, standing orders of a well conducted public health department do not permit the giving of an enema without a specific order from the doctor. In fact, many organizations will not permit a second nursing visit on any case unless first seen by a doctor. Continued nursing care to a patient is rarely permitted without medical supervision. The attitude of these public health organizations is correct since they wish to protect the nurse from practising medicine, and realize that not only is the nurse not licensed or capable of practising medicine but that they do not have the authority to permit her to do so.

An analogous situation exists in industrial medicine where nurses are frequently called upon to work with inadequate or no medical supervision. In order to define their duties, in 1932 the Wisconsin State Medical Society issued "Suggestions for the Guidance of the Nurse in Industry." At the request of nurses, who under wartime conditions

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

were conducting medical departments in industry without the guidance of a physician, in 1943 the Council on Industrial Health of the American Medical Association issued "Standing Orders for Nurses in Industry." In this bulletin, it is suggested, where nurses are working without adequate medical supervision, that written orders be requested from the committee on industrial health of the local or state medical society. Industrial nurses have welcomed these orders and their official organizations consider it an evasion of responsibility on the part of a physician who refuses to sign standing orders for his nurse. The majority of industrial nurses maintain that this procedure gives them legal protection, greater prestige, and greater elasticity of function. Although not basic functions of standing orders, they do provide these benefits if they limit the nurse to nursing practice and truly represent medical supervision in the absence of the doctor.

Field experience with industrial medical departments of many types and sizes in various parts of the country convinces us that the real function of standing orders is not always understood by management, by the majority of nurses, and by many doctors. Generally, two types of interpretations are placed upon their function. One is that its purpose is to give the nurse more leeway than she normally should have, and standing orders really represent permission to practise medicine. We have seen many such orders where a doctor has given permission to the nurse to diagnose, treat, and even suture in his absence. The second type of interpretation is that it is a device to limit the nurse from doing anything but the simplest first aid and record keeping. This type of standing orders reduces the nurse to the status of a record clerk and first aider who refers everything to the physician. The most extreme example that we have seen is one in which a plant

nurse (who was registered and qualified) was instructed in case of doubt to call the physician's office where, in his absence, she would receive instructions from his office nurse.

The term "standing orders" is used rather loosely to cover any act that a nurse may perform in absence of the doctor. Standing orders may be classified in two types—those that relate to situations which recur frequently and those that relate to treatment of a specific patient. The Standing Orders of the American Medical Association and other committees on industrial health are actually outlines for first aid procedures, and the original pamphlet issued by the Wisconsin State Medical Society is entitled "Suggestions for the Guidance of the Nurse in Industry." Nowhere is the word "Standing Orders" used, and in the foreword it is pointed out that it is approved only as an outline of first aid measures.

The necessity for defining the sphere of the nurses' functions in industry is evident in order to avoid a tendency to infringe on the practice of medicine. This situation may be due to management's desire to buy medical care cheaply which may lead the nurses to diagnose, treat, and even suture. They are commonly called upon to do preplacement physical examinations. Nurses, desirous of pleasing management accept the responsibility, but the more conscientious ones, wishing justification, demand standing orders from a doctor. Many standing orders are written by the nurse and signed by a doctor who has no clear concept of his responsibility and who is usually on an "on-call" basis having no responsibility to the plant first aid department except for treating cases as they arise. The nurse thinks that she is now permitted to do things she could not do before, management is satisfied in obtaining medical care for nurses' pay, and the doctor is untroubled as long as no liabil-

ity attaches to his act. Thus, what was intended as a curb on the practice of medicine is used as a license to do so. Doctors who realize their responsibility in creating standing orders refuse to sign equivocal orders which may be construed as permitting the nurse to practise medicine.

Orders which outline procedures for the emergency care of occupational injury or illness are not really standing orders but first aid guides suitable for industry at large, or for a particular industry where certain types of these injuries and illnesses are common. These procedures are carried out within the professional qualifications of a registered nurse without a doctor's authority. However, since each doctor has preferences, these guides state his specific wishes, or if written by a committee on industrial health, outline what is a generally acceptable procedure. Standing orders really relate to treatment of specific patients, and before they can be applied it is necessary that a diagnosis be made, e.g., a standing order for heat to a sprain implies that a diagnosis of sprain has been made. Making a diagnosis is legally the practice of medicine. It can be done only by an individual with proper training and qualifications who is licensed by law after passing an examination. Such authority cannot be delegated.

If medical supervision is adequate, standing orders are not needed, for example, in those industries where full-time plant physicians are in charge. A part-time plant physician whose responsibility is to supervise the nurse may properly issue standing orders to cover some situations in his absence. Since they represent the liaison between doctor and nurse they should be based upon the doctor's regard for the nurse's judgment and ability. In one plant a doctor was willing to write standing orders for one nurse but not for the other. The "on-call" doctor who has no in-plant

responsibility could not and should not be asked to issue orders, but may properly issue a guide for the nurse to follow before referring the case to him. The type of cases which need referral will depend on the ability and professional judgment of the nurse.

It must be recognized that there is a twilight zone where a nurse may properly give care without actually practising medicine. In New York State, excluding injuries which require immediate intensive care such as suturing, the nurse is permitted two maneuvers as first aid measures, that is, care at the onset of injury and one specific re-dressing. A first aid guide may cover these situations, but continued treatment of the patient demands the services of a doctor. If a doctor visits the plant periodically, he will have the opportunity to see the patient and relieve the nurse of the responsibility of continued care without diagnosis.

One function of standing orders is to cover those minor injuries or illnesses which do not demand the services of a doctor. Another function of standing orders is to cover the gap between the initiation of treatment and the visit of the doctor. A third function is to provide standard acceptable procedures for patients with injuries and illnesses which occur frequently in industry. These orders must be created by a doctor, who is not only responsible for the plant medical department but is also responsible for the diagnosis of injured or ill workers. The true function of standing orders does not imply that everything be referred to the doctor. Such orders do not recognize that the nurse is a professionally qualified person who is able to recognize symptoms and signs and to apply nursing procedures which may be effective in safeguarding the life and health of the patient.

The most frequently repeated need for standing orders and the one given the greatest weight by the nurses is that

it affords them legal protection. This view is shared by a number of industrial physicians. It might be well at this point to define legally one who practises medicine. He is defined as "one who holds himself out as being able to diagnose, treat, operate, or prescribe for any human disease, pain, injury, deformity, or physical condition, and who shall offer or undertake, by any means or method to diagnose, treat, operate, or prescribe for any human disease, pain, injury, deformity, or physical condition." Individuals who are permitted to practise must fulfil certain qualifications as prescribed by law. It is obvious that no doctor can give permission for any other person to practise medicine, hence, no doctor can permit a nurse to diagnose, treat, prescribe, or operate. He can permit her to carry out some functions in his absence but must assume full responsibility. There is a definite difference between writing a specific order for a given patient and a standing order for a given condition which a nurse can presumably recognize before the doctor sees the patient. When a nurse carries out an order after the doctor has seen the patient, diagnosed the condition, and prescribed treatment, she is not practising medicine. If she must diagnose and treat then she is practising medicine although she may be following a standing order.

There is no record in New York State of any suit against an industrial nurse for practising medicine with or without standing orders. Legal counsel on this point advises that both the doctor and nurse would be considered responsible if she carried out an order signed by him which could be construed as practising medicine. It is presumed that the nurse knows her limitations, and should refuse to carry out an order beyond her capacities. The law assumes that if the procedure carried out in some cases was within allowable nursing techniques the court would not consider her completely

guilty. It is interesting to note one case in which a nurse was considered practising medicine, who, under direct and personal supervision of a physician, incised the skin in order to enter a vein for a venoclysis. This was considered beyond the scope of nursing.

Every injury in a plant requires first aid treatment, and since the registered nurse is trained to recognize cause and effect of diseases, she is able to take certain measures which are not known to the laymen. For instance, she is trained to care for drugs and to measure dosage accurately, to know the toxicologic effects, and if in an emergency she used these drugs properly it would not be interpreted as the practice of medicine. Legal opinion varies but most lawyers agree that in a serious injury such as a compound fracture, the nurse who gives morphine as an emergency measure before the doctor arrives would not be considered guilty of practising medicine.

To understand the real function of standing orders it is necessary to differentiate clearly between a standing order for treatment as opposed to the so-called standing orders on procedure. The Council of Industrial Health of the American Medical Association, while calling their bulletin "Standing Orders for Nurses," actually promulgated a guide for nursing procedure on injuries and illnesses that may occur within a plant. Such guides on procedures very properly can be issued by medical organizations interested in the field. Real standing orders, however, refer to the treatment of specific patients and can be written only by a doctor who is actively and personally in charge of a dispensary and has the opportunity to see the patient. The "on-call" doctor who is not given direct responsibility for treatment of the cases cannot write valid standing orders but can approve a guide to procedure. The nurse in industry cannot use standing orders from

such a doctor as a substitute for personal medical attention.

Standing orders are meaningful and exercise their true function only when they represent medical supervision in the doctor's absence. Standing orders are not a substitute for medical care and cannot replace the doctor in industry. The practice of industrial medicine will benefit when management, the industrial physician, and the industrial nurse recognize this fact.

Use of Body Measurements in the School Health Program

Part III. Supplementary Note Supplying Measurement and Rating Equivalents for Thickness of Skin and Subcutaneous Tissue below Left Scapula and above Left Ilium

HOWARD V. MEREDITH, PH.D., AND
HAROLD C. STUART, M.D., F.A.P.H.A.

*Iowa Child Welfare Research Station, University of Iowa, Iowa City; and
Department of Maternal and Child Health, Harvard School of
Public Health, Harvard University, Boston, Mass.*

IN Part I of this article¹ the writers recommended that in school health examinations "as a minimum routine of anthropometry seven determinations be made" (p. 1369). The determinations proposed included five measurements (body weight, standing height, chest circumference, hip width, and leg girth) and two ratings (clinical appraisal of amount of subcutaneous tissue in two regions—"slightly below and a little lateral to the inferior angle of the left scapula" and "immediately above the crest of the left ilium" p. 1375).

Part II of the article (p. 1373) discussed specific procedures to be followed and illustrated interpretation of results. It was proposed that the two ratings of subcutaneous tissue be made using a five category scale and employing the symbols +, ++, +++, ++++, +++++.

In deciding whether to recommend ratings or measurements of the quantity of subcutaneous tissue, the writers faced a difficult choice. The advantages of "reliable measurement" were recognized and cognizance was taken of the fact that "a special spring calipers was available for measuring the thickness of folds of skin and subcutaneous tissue." On the other hand, it was apparent that most school physicians are experienced in making subjective ratings of fatty

tissue, while few are proficient in its measurement. We were agreed that "it would not lead to desirable results" to recommend the use of the available instrument "unless the school physician and his assistants were willing to take sufficient time to become skilled in its application" (p. 1369). Our general recommendation was that the quantity of subcutaneous tissue be appraised using the rating approach.

In making this recommendation we did not minimize the fact that the assignment of valid ratings "presupposes a background of information and experience" (p. 1375). It was emphasized that competence as a rater presumes the knowledge that the thickness of the subcutaneous tissue below the scapula and above the ilium "tends to increase with age during the school years and to be greater at any given age in females than in males. It further assumes considerable clinical experience in making judgments of subcutaneous tissue in these areas—experience affording a working familiarity with the range of individual differences found in given age-sex groups" (p. 1375).

The need has arisen for publication of measurement equivalents for ratings +, ++, +++, ++++, +++++. It is to meet this need that Part III has been prepared.

outline precautions that should be taken by certain persons for whom the usual cleaning agents might not be suitable. The *Industrial Hygiene Newsletter* is published by the U. S. Public Health Service, Washington, D. C.

NEW YORK STATE CEREBRAL PALSY

COMMISSION REPORTS

The year-old New York State Legislative Cerebral Palsy Commission recently made a preliminary report to the Department of Health carries over 4,600 such cases on its registers, that another thousand are under the care of the Department of Mental Hygiene, and that approximately one-third of all children in special classes in public schools are victims of cerebral palsy.

At present, although there is no known cure for those who have normal mentality (65 to 75 per cent of all), "there is perhaps no other group for whom rehabilitation to even a slight degree makes so much difference and is so important." The Commission has reached the following conclusions:

1. State care of cerebral palsy victims is inadequate and insufficient although its responsibility for this group is the same as for other disabled groups.
2. Specialized diagnostic and treatment centers should be available at an early age for every child afflicted.
3. Educational, medical, and therapeutic services should be expanded and integrated.
4. Inpatient care should be provided for those in need of such care.
5. At least one model center for diagnosis, treatment, and research should be established as soon as possible.
6. Specialized training for physicians, nurses, and teachers for this field should be stimulated.
7. The present formulae for state and federal assistance for the care of such cases should be restudied.

The first model center to be established will probably be at LeRoy, N. Y., on a fifty acre estate offered to the University of Rochester for that

purpose by Mr. and Mrs. Ernest L. Woodward. Operational costs for treatment services would be supplied by the state, and research and training would be conducted by the university's medical school, Strong Memorial Hospital staff, the National Foundation for Infantile Paralysis, and other groups.

ATOMIC RADIATIONS UNIT FORMED

Dr. J. G. Townsend, Chief of the Industrial Hygiene Division, U. S. Public Health Service, recently announced the formation of an Atomic Radiations Unit in the Chemical Section of the Division. Mr. Duncan Holaday, Engineer (R), is in charge of the new Unit. In making announcement of this new activity, Dr. Townsend expressed the belief that many institutions and industries have been handicapped in their use of radioactive isotopes and high energy machines because of their lack of information about the safe handling of dangerous quantities of radioactive materials. The new Atomic Radiations Unit, working through industrial units in the states, will help institutions and industries evaluate their hazards and establish safe working conditions.

LANSSING-INGHAM COUNTY HEALTH UNIT
The City of Lansing and the County of Ingham in Michigan became a consolidated county health unit on July 1. Its director is Roelof Lanting, M.D., who previously served as Lansing City Health Officer. The combined population (1940) of the city and county is about 130,000.

ON REHABILITATION. DR. KESSLER HEADS NATIONAL COUNCIL

The election of Henry H. Kessler, M.D., as President of the National Council on Rehabilitation (1790 Broadway, New York 19) was recently announced. Dr. Kessler is Chairman of the Council on Industrial Health of the American

university faculty); 35 per cent business proprietors, managers, or skilled trade employees; 15 per cent farmers; and the remaining 10 per cent clerks, carriers, or semi-skilled laborers. The only rejections were rare instances of gross physical pathology" (p. 1384).

Thickness of skin and subcutaneous tissue was measured (1) in the region slightly below and a little lateral to the inferior angle of the left scapula, and (2) in the region immediately above the crest of the left ilium. In each instance, the method employed was that of so placing the measurer's left hand that its palmar surface faced the region of measurement and its first two digits were (a) in an opposable relationship, (b) directed caudally, (c) separated by a distance of approximately 30 to 40 mm., and (d) in contact with the subject's epidermis. The two digits (thumb

and index finger) were then moved directly toward each other in such a manner that a *complete double layer* of the subject's skin and subcutaneous tissue was elevated between them. This elevated fold was held with sufficient firmness to keep its two layers in contact, and the instrument applied to it with the right hand. The flat, blunt-nosed branches of the instrument gripped the fold at the site immediately distal to the tips of the thumb and index finger of the measurer's left hand. After reading off the thickness recorded on the instrument scale, (a) the instrument was removed and (b) the fold slowly released.

Measurements were made on the nude trunk. The objective of the measurer was to draw together a complete double layer of skin and subcutaneous tissue without including any of the underlying

	15-16	17-18	19-22	23-27	28 and up
		17-18	19-22	23-27	28 and up

muscle tissue. Always one or two trial folds were taken in order to adapt the interdigital distance to the firmness and amount of subcutaneous tissue of the individual subject. During measurement, there was constant alertness to see that none of the subcutaneous tissue slipped from between the digits or the branches of the instrument. In the case of the supra-iliac measurement, the calipers were applied approximately 20 mm. superior to the crest of the left ilium in a line vertical with the left axilla. For the measurement on the back of the thorax, the calipers were applied approximately at the intersection of a transverse plane passing through the xiphoid cartilage and a sagittal plane lying midway between the sternum and the lateral wall of the thorax.

The assignment of measurement values to rating categories was made as follows: the lowest 10 per cent of the values for a given age and sex were assigned to category +, the next 20 per cent to category ++, the middle 40 per cent to category +++, the next 20 per cent to category ++++, and the highest 10 per cent to category +++++. Tables 1 and 2 present the results.

Although no further explanation of Tables 1 and 2 is essential, a few statements directly referring the reader to them may serve to elucidate their construction and facilitate their use. Table 1 shows that of the boys age 6 on whom supra-iliac measurements were obtained, 10 per cent gave readings on the Franzen-type spring calipers of 10 or 11, 20 per cent readings of 12 or 13, 40 per cent readings of 14 or 15, 20 per cent

readings of 16, 17, or 18, and 10 per cent readings of 19 or higher.* Girls age 6 will be seen to yield systematically larger readings; for example, while readings of 14 and 15 are "average" records on the boys they are "below average" records on the girls. In terms of rating assignments, given a boy and girl age 6 each with tissue thickness readings of 14, the boy falls in category +++ and the girl in category ++. For tissue thickness readings of 17, rather than 14, the category allocations are +++ in the case of a girl and ++++ on a boy.

Table 2 exhibits the same general age trends and sex relationships as Table 1. Note, for instance, that boys falling in category ++++ at age 5 have the same tissue thickness as girls falling in category +++ at age 5, in category ++ at age 11, and in category + after age 15. Similarly, girls falling in category ++ at ages 15 and 16 have the same tissue thickness as boys falling in category ++++ at age 4, in category ++++ at age 11, and in category +++ at age 18.

Summarizing, this publication constitutes a supplementary note to "Use of Body Measurements in the School Health Program."¹ It provides school health workers with measurement and rating equivalents for thickness of skin and subcutaneous tissue in two regions—above the ilium and below the scapula. Tables of equivalents for normative use are presented on each sex covering the age period 4 to 18 years. The data utilized in constructing the tables were collected 1930–1945 on Iowa City children of northwest European ancestry attending the University of Iowa experimental schools.

Methods to Be Followed in Taking and Interpreting Measurements and Norms to Be Used.* *A.J.P.H.*, 36, 12:1365–1386 (Dec.), 1946.

* For the benefit of those interested in the absolute thickness of skin and subcutaneous tissue during childhood and adolescence, it should be stated that these readings are not in millimeters. In order to obtain the millimeter thickness of a single layer of measured tissue one must first subtract 6 and then divide by 2. Hence, a calipers reading of 10 corresponds to a single layer thickness of 2 mm., a reading of 20 to a single layer thickness of 7 mm., and a reading of 30 to a single layer of thickness of 12 mm.

Simplified Procedure for the Collection of Basic Data for Dental Program Planning and Appraisal*

JOHN W. KNUTSON, D.D.S., DR.P.H., F.A.P.H.A.

*Senior Dental Surgeon, Chief, Dental Section, State Relations Division,
U. S. Public Health Service, Washington, D. C.*

AT no time in the brief history of this organization has the outlook been as encouraging as it is today for the effective application of procedures for controlling the hazards to dental health. Some of the developments and activities which provide the basis for this optimism are:

1. Demonstrations now in progress which hold great promise for the early development of positive methods of preventing specific dental diseases.
2. Widespread endorsement by members of the dental profession of a program to increase dental research facilities and activities, to facilitate education of the public in matters relating to dental health, and to make dental health services available to all.
3. The initiation and sponsorship of legislation which would provide specific financial support for a broader program of research, education, and service.
4. Current dental surveys containing specific provisions for the collection of basic data for community program planning, their use heretofore having been largely limited to epidemiological studies on dental diseases.

To all of us who participate in this increased activity will come greater opportunities for service and heightened enthusiasm in our work program. With these opportunities also will come, to the dental profession and to us as individuals, correspondingly greater re-

sponsibilities. Each increase in public investment for improved dental health, whether in the form of coöperative endeavor, financial support, or both, will enlarge our obligation to provide objective evaluations of our performances.

Increased support of dental health programs—research, education, prevention, and treatment—will be given on the promise of dividends in dental health. Our advance estimates of those dividends may be based on factual information regarding proven control procedures or largely on presumptive evidence. Support based on the latter type of evidence is exemplified by the current willingness of large population groups to finance the artificial fluorination of public water supplies. Although all available data sustain the premise that fluorinated water will reduce the incidence of dental caries, this working hypothesis has not been verified. Yet six cities in this country are now adding fluorine to their water supplies, several cities have formulated concrete plans for fluorination, and numerous others are considering the feasibility of doing likewise.

Thus, it is clear that opportunities to apply methods for improving dental health—methods based on fact or on theory, or both—will increase with expanded support of dental health programs. It is not our intention here to

* Presented before the Dental Health Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 12, 1946.

discourage the utilization of such opportunities to test out on a field trial basis the methods which are unproved. Rather, it is our purpose to urge that all methods and the results of their application be subjected to periodic appraisal.

The workshop technique and the problem-solving approach are terms used today more or less synonymously with program planning. They are founded on the principle that "no health department, state or local, can effectively control disease without knowledge of when, where, and under what conditions cases are occurring."¹ Such knowledge is a prerequisite of effective program planning.

In collecting information on the nature and extent of the dental health problems of a community, answers to specific and pertinent questions are

sought. How prevalent are dental diseases? What are the objective consequences of such diseases? What can be done to control them? What are the community resources for sustaining an effective control program? How can those resources be supplemented and increased in effectiveness? What will the program cost? How can the proposed program be evaluated? Although program evaluation is last on this list of subjects for consideration, there is good reason to believe that it should receive first attention. Just as writing the conclusion of a paper provides direction and purpose to the writing of the body and introduction of the paper, so a definition of the methods to be used in the evaluation or appraisal of a dental program will provide direction and purpose to program planning.

The objective of any program for the

FIGURE 1—Number of Decayed, Missing or Filled (DMF) Permanent Teeth per Person, by Age, for 6,257 Hagerstown, Md., White Children, 2,627 Nicollet County, Minnesota, White Children, and 1,272 Baltimore, Md., Negro Children

control of a specific disease is the elimination or reduction of the consequences of the disease such as illness, disability, or death. Control may be accomplished through the application of preventive or treatment methods. The first of these may be used to eliminate the consequence of the disease through the prevention of its occurrence, whereas the latter may be used to lessen or mitigate the disease or to interrupt its course. Whichever method is used it is essential, in both the planning and the appraisal of the control program, that the prevalence of the disease and its consequences be known.

The prevalence of dental caries, for example, may be measured for the permanent teeth in terms of the average number of decayed, missing, or filled teeth per person, by age. This unit of measurement is adequate for all practical purposes for the age groups 6

through 30 or 35 years, since dental caries is the major cause of loss of permanent teeth during this age span.

Numerous dental surveys have demonstrated that the prevalence of dental caries varies greatly from community to community as well as racially.^{2,3,4} An example of this variation is illustrated in Figure 1 (Table 1). The average number of DMF permanent teeth per child for Nicollet County, Minnesota, white children increases from 0.5 at 6 years of age to 5.5 at 12 years of age and to 11.0 at the age of 18 years; for Hagerstown, Md., white children, the increase is from 0.3 at the age of 6 years to 3.7 at age 12, and to slightly less than 9.0 at age 18. On the other hand, Negro children of Baltimore show an increase from 0.2 at age 6 to slightly more than 2.0 DMF teeth at age 12, the oldest age for which data are available on this last group of children.

It should be noted that the age-specific prevalence of dental caries for each of the three groups of children increases yearly in a straight line manner. Thus the yearly incidence of dental caries can be readily calculated. For Nicollet County white children the incidence would be $11/12$ of a DMF tooth per child per year, for Hagerstown white children $3/4$ of a DMF tooth, and for Baltimore Negro children $1/3$ of a DMF tooth.

Another measure of the prevalence of dental caries in permanent teeth of the children of a community is the proportion of children having the disease by age. An illustration of the character of such information and the differences among the three groups of children previously referred to is presented in Figure 2. It will be noted that beginning with age 6 years the percentage of children having dental caries in permanent teeth increases with age and the rate of increase is different for each of the population groups. At age 12 years, for example, the percentage of children

FIGURE 2—Percentage of Children with at Least One DMF (Decayed, Missing or Filled) Permanent Tooth, by Age, for 6,257 Hagerstown, Md., White Children, 2,627 Nicollet County, Minnesota, White Children and 1,272 Baltimore, Md., Negro Children

FIGURE 3—Relationship of the Per cent of Children with One or More DMF (Decayed, Missing or Filled) Permanent Teeth to the Average Number of DMF Permanent Teeth per child (Paired Age Values), for 5,277 Hagerstown, Md., Children (White), 2,289 Nicollet County, Minnesota (White), and 1,272 Baltimore, Md., Children (Negro)

having caries experience is 93 for Nicollet County whites, 87 for Hagerstown whites, and only 73 for Baltimore Negroes.

Thus it is evident from Figures 1 and 2 that both the percentage of children in a community who have dental caries and the average number of affected teeth per child vary from community to community and that they vary in the same direction. This latter observation led to a study of the relationship of these two measurements to each other and the results of that study are indicated in Figure 3. A common curve from a plot on arithmetic graph paper, of the paired values, percentage of children having caries, and average number of DMF permanent teeth per child, by age, for each group of children. This curve is of the catalytic type (Figure 4) and is described by the

equation $97 - y = 97 (0.524)^x$. A discussion of the formulation, validity, and use of the curve has been presented previously.⁴ It is of considerable importance that the establishment of a standard curvilinear relationship between the two variables permits accurate estimates of the average number of carious permanent teeth per child from observed proportions of children with one or more decayed permanent teeth.

One of the consequences of untreated dental caries is tooth loss. The manner in which this finding varies among the groups of children discussed here is presented in Figure 5. It will be noted that the tooth mortality rate for individuals aged 18 years is two per child for Hagerstown whites, and slightly more than one per child for Nicollet County white children. In view of the previous determination of a higher caries prevalence among Nicollet County

The Welfare Foods Service is concerned with mothers and with children under 5 years of age. As soon as a woman knows she is pregnant she draws a ration book for her unborn child, on presentation of a certificate from a doctor, a midwife, or a public health nurse. She is then entitled to 7 pints of milk a week at less than one-third the market price, or free if she cannot afford to pay. She may also obtain free cod liver oil or vitamin A and D tablets and, for a small payment, a supply of concentrated orange juice. Additional eggs and meat are also allowed her. After the baby is born the mother and child between them may get as much as 14 pints of milk a week, together with vitamin supplements, until the child is a year old. After that the allowance is 7 pints of milk a week for the child till he is five years old and, of course, the normal vitamin supplements. Up to the age of 2 years the child may have national dried milk if it is preferred, as well as an extra allocation of eggs.

So far as milk is concerned the scheme has been about 100 per cent successful, but the "take up" of the orange juice, the cod liver oil, and the vitamin tablets has not been so satisfactory.

When the child reaches school age, i.e., 5 years, he loses the welfare foods but is entitled to the School Milk and Meals Service. He gets $\frac{1}{3}$ pint of milk in school in the middle of the morning and another $\frac{1}{3}$ pint in the afternoon if he wants it. Unfortunately the afternoon milk has had to be discontinued temporarily on account of shortage of supplies. In addition, between the ages of 5 and 18, he is entitled to $\frac{1}{2}$ pint of milk at home every day at the full price. All school milk is now free—over 92 per cent of children in public and private schools are having it.

The school children's milk amounts to about 50 million gallons a year. If this is added to the welfare milk, the

total is 230 million gallons of free or cheap milk for mothers and children, representing about 40 per cent of all supplies.

School dinners in special school canteens are being rapidly extended. At present just over 50 per cent of children attending State-aided schools benefit, but it is intended as soon as may be to provide dinners free for all school children—just now a charge is made for the cost of the food only, roughly about 5d. a meal. Every effort has been made to provide dinners of the highest possible nutritional standard. Extra meat, fat, sugar, and skimmed milk powder have been allowed and the calorie value of the meal for the older children is about 1,000, for the younger 750.

A scheme of family allowances has been introduced in Britain; for each child except the first the parents receive a cash allowance of 5/- a week. There was a considerable demand for a bigger cash allowance but, rather than agree to this, Government decided to give additional benefits in kind by maintaining permanently the Welfare Foods Scheme and the School Milk and Meals Scheme.

5. *Fortification of food*—Margarine had vitamins A and D added to it in January, 1940, to bring its value up to that of summer butter. Later on the amount of vitamin D was increased. This vitamin was also added to national dried milk in 1945 as a safeguard against rickets. Flour has not been fortified. Instead, we have had a national loaf made of 80 to 85 per cent extraction flour, with some calcium added to neutralize the effects of phytic acid, which apparently interferes with the absorption of calcium and iron.

6. An educational campaign on a large scale was undertaken by Government—through the press, on the radio, on the movies, and by local leaflets and demonstrations—to tell the public about the foodstuffs available and how best to

enrolled in the public and parochial schools of the 4 urban centers and 44 rural districts were completed by a dentist and a recorder in a two month period. When the children to be examined are readily available, however, approximately 100 such examinations can be performed in a day. Decoding and processing of the dental examination records required three clerk-months.

The appraisal technic applied in the spring of 1946 was based essentially on information regarding the presence of one or more DMF permanent teeth, and tooth mortality. The former was recorded as plus or minus and the latter by noting teeth extracted and teeth indicated for extraction. Supplemental information not essential to the appraisal consisted of data on the presence or absence of one or more fillings in permanent and in primary teeth. The latter items were recorded as plus or

minus. The tongue blade only was used in making this appraisal survey. The record form used is reproduced in Figure 6. An examiner assisted by a recorder completed the inspections in the equivalent of 9 days. Processing of the data was completed in less than one clerk-week. It is of considerable interest that approximately 1,000 children can be inspected per day by a dentist using this simplified procedure if the children are readily available.

A comparison of the prevalence of dental caries in permanent teeth for the years 1940 and 1946 is presented in Figure 7 (Table 2). It will be noted that for children aged 6 through 11 years the percentages are consistently lower for 1946 than for 1940, but that they are quite similar for children aged 12 to 18 years. Since the mouth mirror and explorer were used in making the examinations in 1940, whereas the tongue

† Extracted teeth and teeth indicated for extraction.

blade only was used in making the inspections in 1946, it seems likely that the differences for children aged 6 to 11 years is a reflection of differences in technique rather than a true difference in caries experience. It is during the age span 6 to 11 years that the first objective evidence of caries in the permanent teeth appears in a relatively large proportion of children. On the other hand, the frequency of such evidence is much greater in children 12 to 18 years old. Comparison of the tooth mortality rates is presented in Figure 8. The rates are consistently lower for each age in 1946 than in 1940 and the overall reduction is approximately 30 per cent.

Information on the proportion of children having one or more filled permanent teeth is presented in Table 2. Roughly 20 per cent more children examined in 1946 had one or more fillings in permanent teeth than children examined in 1940. The relatively high filling experience in 1940 is noteworthy, however, since the findings for this year are used as the basis for demonstrating a further extension of dental service under the program.

According to the data presented in Table 2, a rather marked increase in the proportion of children with one or more filled deciduous teeth was accomplished through the dental program. For

the ages 6 to 12, approximately 50 per cent more children had fillings in deciduous teeth in 1946 than in 1940. It should be emphasized, however, that the information obtained and presented on dental fillings is not essential to basic program evaluation.

Neither program content nor volume of service should influence a clear-cut appraisal of how much control has been effected by a caries control program. For this limited purpose measurements of caries prevalence and tooth mortality are the basic essentials. Many other things of a routine bookkeeping nature must be considered in the complete evaluation of a dental program, such as administrative, educational, and service costs. These have meaning only, however, when related to the relative accomplishments of the program in terms of reduced consequences of dental disease.

The Union Contract and Industrial Hygiene*

BERNARD S. COLEMAN, F.A.P.H.A.

Director, National Council of Jewish Tuberculosis Institutions, Denver, Colo.

THE union contract, now more commonly known as "Union Agreement," is a mutual agreement between the union and the employer, and defines among other things the terms and conditions of employment. According to *Bulletin No. 686* of the U. S. Bureau of Labor Statistics,¹ issued in 1942, the number of union agreements at that time exceeded 50,000, and today in view of the impetus given to a better understanding of labor-management relationships by the activities of the late lamented War Labor Board, the number has been increased greatly.

Although the union agreement is regarded by some people as an anesthetic for the extraction of undue benefits from either management or labor, in reality, it represents an instrument for the better understanding by both parties of those elements or factors which make for sounder labor-management relations and for the improvement of conditions under which industrial practices may be expected to give the maximum results.

In recent years collective bargaining has played an important role in the development of group health insurance and sickness benefit programs. The U. S. Bureau of Labor Statistics reports² that "an increasing number of unions have succeeded in having health-benefit plans included in the terms of their agreements with employees, and

several international unions have established special facilities for helping their locals negotiate such plans. Although a number of the provisions in current agreements signify the substitution of contractual arrangements for already established employer-administered or union-administered benefit plans, many of them are new; some of the latter have been negotiated in lieu of wage increases which could not be obtained under the wartime wage stabilization program."

Group health insurance programs have been available in some companies for some time, but they were usually administered by the employer and could be altered or discontinued at the will of the company. It has been claimed that many were started merely to win employee loyalty and discourage union organization.² The motives for the establishment of these plans were continually under suspicion and as a result organized labor had never whole-heartedly endorsed them.

With the advent, however, of union participation in the plans to the extent of their inclusion in the union agreement, the attitude of labor on this score has changed considerably, and today we find health benefit programs, although for the greater part paid for entirely by industry, jointly administered by management and labor, or in some instances administered entirely by the union.

Examples are the union agreements initiated by the Amalgamated Clothing Workers and the United Retail, Whole-

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Twenty-fourth Annual Meeting in Cleveland, Ohio, November 13, 1946.

sale and Department Store Employees Unions which call upon the employers to pay a percentage of the payroll into the fund which, in turn, is administered jointly by the employers and the unions. The International Ladies Garment Workers Union and the Hat, Cap and Millinery Workers Unions administer the fund made available by a gross payroll tax contributed by the employers. The Textile Workers, CIO, fund is employer financed, and administered by insurance companies. The National Bituminous Wage Agreement, effective during the period of government operation of mines, provides a health and welfare program, the welfare and retirement fund being supported exclusively by the operators and managed by three trustees, one appointed by the Coal Mines Administrator, one appointed by the President of the United Mine Workers, and the third chosen by the other two. Furthermore, the trustees administer the medical and hospital fund accumulated from wage deductions authorized by the union.

It is true that in general greater emphasis is being placed on group health insurance and sickness benefit plans in collective bargaining than on basic industrial hygiene factors and principles. One of the most comprehensive series of clauses pertaining to health, safety, and medical care is that of the United Mine Workers, which clearly places industrial hygiene in as important a category as issues of wages and union security. In addition to their health and welfare program referred to above, "the Coal Mines Administrator undertakes to have made a comprehensive survey and study of the hospital and medical facilities, medical treatment, sanitary and housing conditions in the coal mining areas. The purpose of this survey will be to determine the character and scope of improvements which should be made to provide the mine workers of the nation with medical, housing, and

sanitary facilities conforming to recognized American standards."³ Thus, the supervision of industrial hazards takes its proper place in the consideration of the health and welfare of the worker.

The rapid movement of demands by unions for health and welfare service from employers does not, in the true sense, actually involve industrial hygiene, according to Dr. Leo Price, Director of the Union Health Center, who stated: "As far as unions are concerned, emphasis has been shifted from industrial hygiene to social security and health service for workers. All the union contracts in the garment industry which have secured a payroll tax levy stipulate it should be spent for vacation benefits and health services such as medical care, sickness and hospitalization benefits and death benefits."⁴

Nevertheless, there is ample evidence of the increasing interest on the part of labor to include various industrial hygiene provisions in union agreements. A study⁵ of union agreements in effect twenty years ago reveals various provisions relative to the safety and comfort of employees already existent at that time. Clauses called for suitable fire protection, the observation of sanitary codes, satisfactory sanitary arrangements, adequate dressing rooms, lockers, wash rooms, toilets, and cold drinking water. Some clauses called for cleanliness and sanitary conditions with sufficient heat, light, and ventilation. Suction devices were to be provided for dust-raising machines. The clauses, however, were all very meager and were but the beginning of more comprehensive clauses in later years.

The International Union of United Automobile, Aircraft and Agricultural Implement Workers of America (UAW-CIO) has issued a publication⁶ containing sample clauses recommended for all local unions by the International Executive Board which are quite comprehensive. The recommendations call

for a health and safety committee consisting of company and union representatives. The duties of this committee are outlined specifically and if followed should make for a comprehensive industrial hygiene program. Furthermore, the agreement outlines the company's industrial hygiene responsibility to the effect primarily that the company shall "maintain sanitary, safe and healthful working conditions in the plant, to equip all hazardous machinery with effective safety devices, to maintain precautions against exposure which may cause occupational diseases or other symptoms, and to furnish and maintain without cost to the employee whatever equipment and clothing may be needed by them for the safe, healthful, and protective performance of their jobs." Provisions are made for the reporting of all industrial injuries, diseases, and absences due to illness to the health and safety committee, for the maintenance of the necessary medical facilities for the treatment of injured employees and the limitations to be placed on the services to be rendered by first aid men and nurses. The agreement specifies that physical examinations shall be made and the results be held confidential, and that such physical examinations "shall be used solely for the purpose of proper placement," and that any changes in the employee's position that may result from physical examination shall be referred to the health and safety committee for investigation.

The above requirements seem to be reasonable and logical. With mutual understanding of the importance of maintaining healthful working conditions for the protection and health of the worker, there is no question but that proper and adequate results can be obtained. At least it puts the company on notice that labor expects the conditions that industrial hygienists have been pleading for these many years. Ever so many

surveys indicate the relative infrequency of good industrial hygiene services. If those companies in which there are union agreements will write into the contract the industrial hygiene clauses that are recommended and the companies as well as the employees carry out the provisions, one of the greatest steps forward in industrial hygiene will have been taken.

Unfortunately the local union agreements are not generally as comprehensive as those recommended above, but there are sufficient numbers to indicate the development of an industrial hygiene consciousness on the part of management and labor.

Several union agreements that have been reviewed still make reference merely to adherence to legal requirements and thus dismiss the subject. Another type of agreement emphasizes cleanliness of toilets and wash rooms, while others state only that the company agrees to provide healthful working conditions. An aircraft company includes in its union agreement clauses on physical examinations, plant sanitation, exhaust ventilation, first aid, health and safety committees. In a shipbuilding agreement the industrial hygiene considerations are embodied in one clause, as follows:

"All toilets and washrooms shall be kept in a clean and sanitary condition, properly heated and ventilated, and suitable quarters with heat shall be provided for men to change clothes and eat their lunch. There shall be facilities for drying clothing; and all staging, walks, ladders, gang planks, and safety appliances shall be constructed in a safe and proper manner by competent mechanics. Proper lighting and ventilation shall be provided for all enclosed working spaces. The employer shall furnish suitable guards around welders for the protection of workmen's eyes. In case of spray painting, employer shall provide proper protection against fumes caused by paint spray. Prompt ambulance service and first aid to injured workmen shall be provided on all shifts, and a safety man shall be employed and made responsible for the

proper enforcement of safety rules. Suitable lockers, washrooms, and drinking water shall be furnished by the employer. There shall be no doctor's physical examination nor age limit, except as required by law. Unless required by law, no employee shall be compelled to pay hospital or insurance fees in the course of employment or as a condition to secure employment."

The safety director of a company, which has the following industrial hygiene clauses in its agreement with the union, feels that the reference to union recognition of the employees' duty to cooperate with the company in its safety and health program is "a great step forward in union and management cooperation in the health and safety of workers in an industrial plant":

"The Company recognizes its obligation under the law of the Local, State and Federal Governments, with reference to the health and safety of its employees, and shall continue to comply therewith. In the event such laws are inadequate to insure proper protection to its employees, the Company agrees to make every reasonable effort to eliminate all unsafe or unhealthy conditions. The Union recognizes the duty of the employees to cooperate with the Company in its safety and health program when approved by the Union."

"A joint safety committee composed of equal representatives of the Company and the Union shall investigate all accidents and take all necessary steps to prevent accidents."

"The Company will furnish all necessary equipment such as special gloves for handling hot metal, goggles, respirators and other such articles required by safety codes."

"All lavatory and wash room facilities will be kept clean and sanitary in addition to being provided with soap and adequate lockers."

The following agreement is a splendid example of effective industrial hygiene clauses which both labor and management have found to be highly beneficial, for the joint Safety Committee is interested in all phases of conditions relative to the working conditions, safety standards, and other conditions affecting the employees' health and well-being; furthermore, the committee is

well versed in the safety standards prescribed by the Department of Labor and Industries for the State, and is continually striving for the betterment of the safety conditions and welfare of the employees:

Physical Examinations—

"Every applicant for employment must pass a physical examination. If, by such examination the applicant is rejected for employment, he will be furnished with the doctor's report upon request. The applicant shall then have the privilege of having an examination by a qualified physician of his own choosing. If the two reports are contradictory, the Union may then take the matter through the regular grievance channels. The cost of examination by his own physician shall be paid by the applicant."

Plant Safety Committee—

"It is the desire of both parties to this agreement to maintain high standards of safety in the plants of the company in order to eliminate as far as possible industrial accidents and illnesses."

"Plant Safety Committees shall be appointed from employees at each of the Company's plants not exceeding four representing the Union and four representing the Company. The chairmanship of these committees shall be rotated between the Union and the Company members each quarter. The secretary shall be chosen from the opposite group to the chairman and shall keep minutes of all meetings."

"The duty of the Plant Safety Committees will be to see that all applicable state and municipal safety and sanitary regulations are complied with as well as to make recommendations for the maintenance of proper standards. These committees shall receive and investigate complaints regarding unsafe and unsanitary working conditions."

"The Company shall have available at all times in each shop, a supply of safety report forms, made up in quadruplicate for the use of shop committeemen and foremen to report any needed correction in the shop relative to safety conditions. One copy of this report will be sent to the chairman of the safety committee, one copy to the President of the Union, and one copy to the Company Safety Supervisor. The original copy of the report will remain in the shop files, which shall be available at all times to the shop committee. The Company safety supervisor will keep the above named persons informed in writing of

the progress, disposition and adjustment of each such safety report.

"Proper and modern safety devices shall be provided for all employees working on unsafe and hazardous work, such devices to be furnished by the Company, and it shall be mandatory for employees to use same.

First Aid—

"The Company at all times shall maintain on all shifts, in all plants, sufficient registered nurses and emergency first aid stations to care for employees in case of accidental injuries.

"The Company shall provide ambulance service for all shifts in all plants.

Sanitation—

"All toilets and wash rooms shall be kept in a clean and sanitary condition and suitable quarters with heat shall be provided for men to change clothes and their lunch. There shall be facilities for drying clothes, and all staging, walks, ladders, gang planks and safety appliances shall be constructed in a safe and proper manner by competent mechanics. Proper ventilation shall be provided and welders shall have guards around their work to protect workmen's eyes. Arrangements must be made to give prompt ambulance service and first-aid to injured workmen, and a safety man shall be provided on all shifts, if necessary, and made responsible for the proper enforcement of safety rules. The Business Representatives of the various crafts shall have access to the shops and yards at all times by applying for permission through the office, provided they do not interfere with or cause workmen to neglect their work. Shower baths shall be installed where tank and boiler cleaning work is done.

Control of Hazards—

"All equipment and processes that emit or create harmful dusts, fumes, vapors or gases in quantities, that create harmful exposure to employees exposed thereto and where the prevention, elimination, or control of said hazards by means of general ventilation alone are inadequate to furnish the required protection, shall be connected to an exhaust system for the removal of said hazards as far as practicable at their point of origin."

An industrialist in a personal communication recently stated: "In contract negotiations in recent years, the matter of so-called industrial hygiene or safety clauses has been discussed. In

view of the health maintenance program and the extensive safety program in existence in all our plants, and the record of performance which has been achieved as a result of these programs, our position in this respect is different from that which might be obtained in other industrial enterprises not having the same performance record.

"In the matter of industrial hygiene or accident prevention work, management, in the final analysis, is charged with the responsibility for the conditions which exist in an industrial enterprise. Accordingly, we believe that since the responsibility rests with management, the execution of such responsibility must also rest with management. On the other hand, this does not mean that we discourage interest on the part of our employees in making suggestions or taking an active part in making our plants safer and healthier places in which to work. In fact, the Company's Suggestion Plan provides a means whereby employees may receive financial reward for making suggestions for the improvement of safe working conditions."

Industrial medical services, including health and safety activities, have been for the greater part the sole responsibility of management until the last few years. There is fragmentary evidence of references to health and safety in union agreements in effect twenty years ago, but within the last two decades organized labor has taken an increased interest in industrial health services and if this movement takes on the anticipated impetus, management will be compelled to pay more attention to the environment in which the employee works. Everything points to a more consummate effort on the part of management to introduce and maintain the most modern medical services that are attainable.

Whether this will come as a result of the insistence of labor to include industrial hygiene clauses in the union agreement, whether it will come about by management's voluntary contribution, or whether it will result from

mutual coöperation between management and labor, is of relative significance, but that industrial management operations for effective production demand some such consideration is the crux of the development of adequate industrial medical services at all times in all industries.

Above all, industrial hygienists everywhere have a golden opportunity to enhance their field by enlisting the support of labor, and to this end the Union

Agreement can be an effective instrument.

AMERICAN PUBLIC HEALTH ASSOCIATION

Postcensal Population Data for Cities*

HENRY S. SHRYOCK, JR., PH.D.

U. S. Bureau of the Census, Washington, D. C.

SINCE 1940 there have been spectacular rises in the numbers of marriages and births in the United States. Further gains have been made in death control, with unanticipated special progress in reducing the toll of certain diseases. Fifteen million men and women entered the armed forces, of whom only 1,300,000 now remain there. The growth of cities was affected not only by these factors, but also by a record amount of internal migration, on the part of both civilians and troops.

Amid all these changes, the vital statistician needs postcensal population figures more than ever. He wants to compute the birth, death, and marriage rates for his city during the war and post-war years. The public health administrator is interested in the size of the population he must serve and in its racial, personal, social, and economic characteristics. He wants to know what effects of the war upon urban populations are relatively permanent and to what extent pre-war levels and trends are being reestablished.

You are probably keenly aware that the Bureau of the Census does not have annual postcensal population estimates for all cities, even those above a certain size. It is unlikely to have such estimates in the near future. On the positive side, however, it should be said that the demographic changes of the

period since 1940 are far better chronicled than those of any previous period in American history except for the census years themselves. This is particularly true on the national level; but an unprecedentedly large amount of data have also been collected and published for states, counties, and cities. These gains are partly overshadowed by the very magnitude of the changes that have occurred and by the rapid growth in the public's demand for statistics.

Before summarizing the population data now available for cities, I should like to discuss briefly the possible population figures for an area. In a decennial federal census, the population shown for a state or city is essentially the *de jure* population, that is, the number of people whose usual residence is in the area. Members of the armed forces are counted where they are stationed. During the war there was an understandable desire on the part of a city to have its former residents absent in the armed forces counted as part of its population. For several reasons, such a procedure was impracticable. No one knew how many men inducted from the city had families there to report them. The total number of men entering the armed forces included some who had died or had already been discharged and settled elsewhere; some still in the service would die in the service or settle elsewhere upon their discharge. Therefore, the Census Bureau never counted such persons in local censuses or included them in estimates.

* Presented before the Vital Statistics Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 14, 1946.

It was possible to include troops stationed in an area in the censuses and some of the estimates. The sum of the troops and the resident civilians does not constitute, however, the *de facto* population of the area. On the contrary, this sum is comparable with the decennial census figures, since civilians temporarily absent were included and those only visiting in the area were excluded.

Realistically, however, it was recognized that the troops stationed in a city were a very transitory part of its population. In many ways they were not the responsibility of the city government. Therefore, whenever security regulations permitted, they were shown separately. At other times, only the civilian population was enumerated or estimated. In computing birth rates for states, the National Office of Vital Statistics has used the resident civilian population as a base. In computing death rates, it has used the civilian population plus the troops stationed in the area.

At the request and expense of local governments, the Census Bureau has conducted about 250 special censuses since 1940. Most have been of cities, but others covered counties, minor civil divisions, or new annexations to a city. These censuses represent complete counts of the military and civilian populations in the area. The Bureau provides the supervisor (for whose services it is remunerated), schedules, and procedural instructions. It tabulates the data, certifies the figures as official, and publishes the results.¹

Most local governments request only a cross-classification of their population by sex and race, but the larger ones usually are also interested in the distribution by age. If the city is tracted, the data are tabulated by census tracts. The number of occupied dwelling units, which is equivalent to the number of private households, is almost always ob-

tained. If the sponsoring government desires, the schedule will cover additional characteristics of population and housing.

Most of the cities that have sponsored special censuses have been in California, but there have been a fair number in other parts of the country. The larger places canvassed include Berkeley, Long Beach, Los Angeles, Oakland, Sacramento, San Diego, and San Francisco, Calif.; Beaumont and Port Arthur, Tex.; and Wilmington, N. C.

In 1944 the President's Commission on Congested Production Areas asked the Bureau to conduct sample censuses in the more important such areas. Those enumerated were: The Puget Sound, Portland-Vancouver, San Francisco Bay, Los Angeles, and San Diego areas on the West Coast; the Detroit-Willow Run and Muskegon areas in the Middle West; and the Hampton Roads, Charleston, S. C., and Mobile areas in the South. The total population of each area was obtained with a coefficient of variation of less than 1 per cent, i. e., 2 out of 3 times an estimated value should fall within 1 per cent of the complete count. Estimates of the total and civilian populations were published for 22 cities in these areas.² In addition to these resident populations, the population actually present on the census date (the *de facto* population) was shown.

Published data from these sample censuses covered a wide variety of characteristics. These included sex, race, age, marital status, and relationship to head of household; number, origin, and characteristics of immigrants; employment status; and characteristics of housing.

Chiefly on the basis of the number of registrations for ration books, estimates were made of the civilian population of counties as of May, 1942; March, 1943; and November, 1943.³ By

now, station strength in a particular county on these dates is obtainable from the War and Navy Departments. This military population may be added if the total population is desired. Only a few cities coincide with these counties, it is true; but in the case of many of the larger cities, the county population provides a useful ceiling in the preparation of an estimate. For the last date, November, 1943, the estimated age and sex distribution was also published for 39 areas of intense war activity.⁴

Beginning in 1942, the Census Bureau, in coöperation with the National Housing Administration, has conducted numerous housing surveys in urban areas, on a sample basis. Of these, 250 have estimated the number of occupied and vacant private dwelling units in the city.⁵ Tenure and persons per room are reported for the occupied dwelling units and habitability for the vacant ones. Similar studies have been conducted in a number of large cities by the Bureau of Labor Statistics. Urban surveys have been made to determine the housing intentions of veterans.⁶ To date press releases for 113 areas have been published. Among other facts reported is whether the veteran lived in the area at the time of his entry into the armed forces, an item which indicates the extent of in-migration of veterans.

It may be of interest that wartime migrants, in general, have not returned in large numbers since V-J Day to their old homes. The centers of war production are tending to hold on to their gains, according to several surveys made by the Census Bureau. Furthermore, the volume of internal migration has continued to be large in the first year of peace. Many veterans are settling in new homes, and their destinations are similar to those chosen by civilian migrants during the war.

There are prospects for a fair number

of additional population estimates between now and 1950. In October, November, and December, 1946, sample surveys of the nature of the Census Bureau's *Monthly Report on the Labor Force* were taken in a number of local areas. Twenty-five cities and 8 metropolitan districts were covered. Although these surveys were designed primarily to obtain facts about the labor force, the total civilian population was also secured as a by-product. The sample was designed to secure such estimates with a coefficient of variation due to sampling error of 5 per cent.

In April, 1947, an expanded national survey of the labor force, population, and housing was undertaken. Special surveys were also taken in each of 35 metropolitan districts. Three releases have been published for each district: one on population, one on the labor force, and one on housing.⁷ An estimate of the population of each metropolitan district is given in the first release. If funds are available, the rest of the 140 metropolitan districts will be covered during 1948 or 1949. These surveys will be similar to those taken in the fall of 1946 rather than to the April survey. It is hoped that estimates of population for cities may be published eventually on the basis of the sample surveys supplemented by independent contemporary data.

The Bureau would have conducted a national sample survey in October, 1946, had the necessary funds been appropriated by the Congress. In fact, funds for preparatory work on this sample were provided in the fiscal year 1946; and in the special census of Wilmington, N. C., taken in April, 1946, the schedule for a national sample census and some of the procedures were pre-tested. As a result of the preparatory schedule testing, and other preparatory work, the Bureau is prepared to conduct a national sample survey of population once funds are available.

Such a national sample would permit the publication of estimates with a coefficient of variation of about 1.5 per cent for all states and for all cities above a certain minimum size, say 150,000. The composition of the population of these states and cities would also be shown.

Finally, a word may be said about population censuses conducted by the states. Unfortunately, only a small fraction of the states that performed this function several decades ago do so nowadays. In the forties only Florida, Kansas, Massachusetts, and South Dakota have taken censuses. The coverage is on a complete, rather than a sample basis; and figures are published for all incorporated places. The quality of these enumerations varies, and all make a practice of trying to include persons living in the area at the time of their entry into the armed forces but living outside the area at the time of the census.

Meanwhile, the problem of current estimates of city population remains with us. Aside from the ration book registrations and sample surveys, no important new source of estimates has appeared during the forties. As the foregoing resume of available data indicates, however, one does not always need to go back to 1940 as a base date.

It has been often noted that local series sensitive to economic fluctuations are usually poor indices of population growth.⁸ In this class, I should put the number of electric, gas, and water meters; the number of telephone subscribers; newspaper circulation; and bank clearings. Early in the war, these series often ran ahead of population growth because their increases reflected mainly the added prosperity of the inhabitants. Later in the war the reverse was often true, since the in-migrants could not get utilities because of shortages or had to double up with other families. Similarly, statistics on building

permits and demolitions; usually of moderate aid in making estimates of families, became of restricted use because shortages have limited the new construction needed to take care of the greater number of families in the city.

Where there is a good city directory, the number of listings of individuals may be used in estimating the adult population. The process is expensive and must be carried out carefully. For instance, suburban residents, wives listed separately as well as with their husbands, and business firms should be eliminated. A well designed sample will cut down the expense and give an estimate of the net listings within a determinable sampling error. The population of school age may be estimated from school enrollment statistics or a school census. All these series should be obtained for the base date as well as the estimate date so that the ratio between the series and the equivalent census age group may be established. Finally, children of preschool age may be estimated from resident births. The parts are added to get the estimate of the total population. Note that the post-censal source used does not have to represent a complete coverage of the age group concerned. It is necessary only that the source bear a fairly constant ratio to the population group or that this ratio vary in a predictable manner.

If a recent city directory is not available, one may use vital statistics and school data alone. The natural increase of the city population is first estimated from resident births and deaths. The school data may be used to gauge net migration. Get the ratio of elementary school enrollment or the local school census to a comparable age group in the 1940 census. Using survival rates derived from an appropriate life table, one may next compute the expected number of survivors from the 1940 census in this age group at the estimate date.*

* The number of children at ages below 5 in the 1940 census should be corrected for underenumeration.

This is the number expected had there been no migration. Using the 1940 ratio of the local school statistic to the federal census age group (or an extrapolated value of the ratio), translate this estimate into the expected school enrollment or school census at the estimate date. The difference between the expected and the actual number is an estimate of the net migration in or out for this age group. The simplest assumption is that the rate of net migration can be applied to the population of all ages. In some cases, other assumptions may be made on the basis of additional evidence. For example, it may seem better to assume that the net migration proportion was 50 per cent greater for the population of all ages.⁹

The number of men taken from the city's population into the armed forces through given dates should be obtainable from local selective service boards. It is possible that data on discharges may also be available locally; if not, a factor based on the nation's experience could be used to estimate net loss to the armed forces. The resulting estimate should be subtracted from the population at the base date as an additional step in getting the civilian population. If the total resident population in the city is desired, add the number of troops stationed there at the given postcensal date.

I have given above rough outlines of two types of methods of estimation. These outlines indicate the general approach and are not intended to serve as detailed directions for making a particular estimate. The complete methods would require several pages and even then would not take into account unique problems that might arise in particular cities.

The best population estimates for cities will not be obtained by applying a rigid formula to all cases. Local statisticians are in the best position to investigate the peculiarities in the symp-

tomatic data available for their cities. Some cities have sources that do not exist in others. The Bureau of the Census is now struggling with estimates of state population for July 1, 1947. At present it does not have the facilities to tackle the problem for cities. We should be happy, however, to correspond or consult with statisticians who are making serious attempts to produce estimates for their cities. Such discussions of investigation and experimentation should prove of mutual benefit in uncovering new sources of estimates and in improving methodology.

Women's Clubs Support Cancer and Heart Programs

The Business and Professional Women's Clubs of New York State, at their 28th Annual Convention in May, adopted the following resolutions submitted by their Health Committee Chairman, Sue Thompson Gould, M.D., then Commissioner of the Columbia County Department of Health:

1. That each club stimulate the promotion of a Cancer Detection Clinic through its

county medical society if one has not already been established.

2. That the Business and Professional Women's Clubs of New York State, Inc., through its individual clubs cooperate actively and lend its support to programs of education, research, and service for Heart Disease.

3. That the Business and Professional Women's Clubs of New York State, Inc., through its individual clubs supports the American Heart Association in its effort to establish a county heart association wherever one has not already been established.

Diagnostic Procedures for Gonococcal Infection

Summary of a Panel Discussion *

STAFF members of three laboratories in Baltimore, Md., engaged in routine isolation of the gonococcus maintained an active exchange of experiences through conferences held throughout the past two years. In the first paper they presented a detailed *critique* based on the chapter "The Gonococcus" in the second edition of *Diagnostic Procedures and Reagents*. The purpose was to reach some general agreement on certain points, to clarify the problems most in need of further investigation, and to suggest important features for possible revision.

The comments can, in general, be grouped under three headings: points on which there is evident need for further study, predominantly those on which the three laboratories found themselves at variance; points which should be amplified by the inclusion of additional or alternative methods, several of which have been published subsequent to publication of the chapter; and points

which might be clarified by changes in the language of the text.

Those subjects suggested as needing further study cover practically the entire range of the problem, including: the relative merits of wet and dry swabs, the liquid to be used as a moistening agent for them, the choice of suspension media, methods of inoculating plates, the media to be used, the need for nutritional "supplements" and for inhibiting agents both for repressing growth of extraneous organisms and for counteracting the effect of therapeutic drugs, the relative sensitivity of all suggested modifications of media as studied in large enough series to be statistically significant, methods of transportation including refrigeration and shipment by mail, the establishment of schedules for smears and cultures for determining bacteriological cure, the validity of all methods for this purpose, and the value of the examination of urine, prostatic secretions, and paraurethral and cervical

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-fourth Annual Meeting in Cleveland, Ohio, November 11, 1946.

A Comparative Study of Media for the Primary Isolation of the Gonococcus. Thomas H. Weller, M.D., Children's Hospital, Boston, Massachusetts.

swabs. Further study of the microscopic smear technic is suggested particularly in respect to the significance and classification of various atypical findings and the standardization of terminology in evaluating and reporting such results.

Alternative or additional methods are suggested for: inoculation procedures, the direct inoculation of plates from the original swab without emulsification and centrifugation, and the inoculation of chocolate broth tubes and agar slants in addition to plates in the case of blood cultures and joint and spinal fluid cultures; the choice of media, permitting the use of several of the newer modifications; the use of "spotting" as well as "flooding" technics in examining plates for oxidase reactions; the choice of carbohydrates for confirmatory tests, especially the possible omission of lactose for such purpose in routine work.

Direct disagreement with the present chapter is expressed in two particulars: the use of poured plates for blood cultures is considered inadvisable, and exception is taken to the statement that continued examination of smears containing extracellular diplococci will *usually* reveal intracellular organisms. It is also suggested that the chapter might be improved by the inclusion of some colored plates and that the section on complement-fixation should be subordinated, since this procedure is not in general use.

Some clarification in the wording of the chapter is suggested, particularly in respect to those portions dealing with the choice of microscopic or cultural methods or their simultaneous use, the classification of smear findings, the interpretation and reporting of the presence and relative number of pus cells, the definition of "false" positive and negative findings, the amount of carbon dioxide present in candle incubation jars, the carbohydrates to be used for confirmation, and the exact wording of reports.

Accompanying this *critique* the same authors submitted a brief resumé of experimental data accumulated during their investigations. Of a total of 183 smears examined in the three laboratories, complete agreement was reached on only 98 smears; in an additional 76 smears two laboratories agreed, while a third was at variance; and on 9 smears each laboratory reported a different finding. Tests of the various plating media were made by having each laboratory prepare the medium which it was routinely using and having these plates inoculated by the same person from the same sulfathiazole resistant case of gonorrhea. Sixteen such cases were evaluated on five different media: Difco with supplement A, Difco with supplement B and 3 per cent ox serum, cysteine chocolate agar, Mueller's medium, and Cohn's medium. Positive cultures ranged from 11 and 10 on the first three media to 8 and 5 on the two last named. When the three laboratories prepared the same medium, Difco with supplement A, only minor differences were noted although of 14 cases tested in this manner positive findings varied from 12 to 10 in the different laboratories. No difference was noted in a similar experiment using three different lots of hemoglobin.

T. C. Buck, Jr., of the Baltimore City Laboratory, studied a series of urine cultures. The first 15 mL. of urine from each patient was plated as soon as possible. In addition, urethral exudate was obtained and cultured within 10 seconds. This material was collected without prostatic massage and after sulfonamide treatment from 346 asymptomatic males. Urethral cultures were positive and urine cultures negative in 28 cases, while urine cultures were positive and urethral cultures negative in 12 cases. An additional 36 cases yielded positive cultures by both methods.

The Hopkins Laboratory suspended 19 strains of the gonococcus in Proteose

peptone No. 3 with 0.5 per cent sodium chloride, pH 7.6, and made subcultures with minimum inocula at intervals of 1, 2, 4, 6, and 18 hours. One strain was lost in 1 hour, 6 additional strains in 4 hours, 5 more in 6 hours, and by the end of 18 hours 15 of the original 19 strains had been lost.

Mr. Buck also tried a new transportation medium of gelatin agar glycerine base supplemented with fresh egg albumin and ox serum or Difco supplement A.* Of 313 specimens examined 237 were positive on direct plating within 10 seconds after obtaining the specimens from the patient, and 185 after holding 26 to 28 hours at room temperature before plating.

The Hopkins Laboratory also experimented with the use of clarase in addition to supplement A in Difco medium in the presence of penicillin. Clarase itself was not inhibitory and its use permitted the recovery of gonococci which otherwise would be inhibited by penicillin. This laboratory also compared 24 hour with 48 hour plate readings on clinical cultures on Difco medium and found, in a series of 54 cases, 22 which were negative on 24 hour and positive on 48 hour incubation. An additional study indicated that phenol red could be substituted for Andrade indicator in fermentation media.

The remainder of the panel discussion was devoted to the presentation and discussion of a series of papers containing the results of recent investigations by other laboratories.

Dr. J. D. Thayer presented excerpts from four papers from the Venereal Disease Research Laboratory of the U. S. Public Health Service.† He first showed comparative results obtained in the primary isolation of the gonococcus using Peizer medium, Difco Bacto proteose No. 3 agar and hemoglobin,

Mueller-Hinton medium, and a modification of McLeod's medium. For primary isolation the modified McLeod's medium gave 9 per cent more positive cultures than did Peizer, 17 per cent more than Difco, and 32 per cent more than Mueller. It was also superior in the number of colonies appearing on the plates. Of the countable plates in the series, McLeod's medium averaged 58.8 colonies per plate as compared with 39.6 on Peizer, 37.9 on Difco, and 10.2 on Mueller-Hinton; while on those plates containing too many colonies to make an accurate count, more were graded 4+ with the McLeod medium than with the others. A comparison of inoculating the medium with the swab immediately, i.e., at the patient's bedside, with inoculations after a 3 hour period of storage in broth at room temperature showed the former method to be superior, yielding 96.5 per cent positive plates as compared with 77.2 per cent. Cysteine has been recommended for addition to media to increase the survival of gonococci but experiments showed that it had no such effect. Experiments on delayed incubation of inoculated plates showed that storage of such plates in an atmosphere of 10 per cent carbon dioxide favored the survival of the gonococcus; 96.6 per cent plates so stored were positive as against 71.1 per cent stored in a normal atmosphere. Primary isolation and identification of the gonococcus on

plates of Peizer medium containing glucose and maltose with neutral red as indicator according to the method reported by Weckstein proved unsatisfactory in the hands of the author since 64 per cent of the plates gave atypical reactions. Finally mention is made of the necessity of neutralizing the oxidase reagent *p*-aminodimethylaniline hydrochloride with sodium carbonate to avoid atypical reactions.

Lenore Peizer presented a series of studies on the efficiency of transportation methods for gonorrheal specimens. The same swab was used to inoculate transportation media and control plates of plasma hemoglobin agar. Control plates were incubated within 6 hours of the collection of the specimens, transportation media after storing at room temperature for 24 hours. All cultures were incubated in 8 to 10 per cent carbon dioxide at 36°C. for a period of 40 hours. Of 257 specimens from females, 62 gonococcus cultures were obtained from control plates and 18 from Hirschberg chocolate gelatin, Nile blue A agar. Of 745 similar specimens, 197 gonococcus cultures were obtained from control plates and 173 from slanted plasma hemoglobin agar in tubes containing 10 per cent carbon dioxide, according to the method of Usher and Stein, the tubes in this series being examined after 24 hour as well as 40 hour incubation periods. Of 1,260 specimens from both males and females, 483 gonococcus cultures were obtained from control plates and 459 from a 1/4 inch layer of plasma hemoglobin agar in rectangular bottles as recommended by McClure and Miller.

The effect of delayed incubation with Hirschberg medium was studied on a series of 87 specimens from males with acute gonorrhea. All 87 specimens were positive on control plates incubated within 6 hours, 84 were positive on plates and 18 on Hirschberg medium incubated after 24 hours, 43 were posi-

tive on plates and 7 on Hirschberg medium after 48 hours, and 9 were positive on plates and none on Hirschberg medium after 72 hours.

Dr. Nell Hirschberg presented a summary of the present status of methods for the transportation of specimens for gonococcus culture. The literature was briefly reviewed and the following reports were selected as those that have influenced others to try out the methods: Greene in 1938 advocated the use of swabs impregnated with sterile ascitic fluid for making smears, stating that the preliminary incubation of these swabs increased the number of intracellular organisms; Cox in 1942-1943 first advocated a horse blood solution with 1:30,000 gentian violet and later horse serum with 1:800,000 gentian violet; Peizer in 1943 reported the use of plasma hemoglobin cysteine agar and Stein described the use of Peizer's medium in tubes into which carbon dioxide had been introduced; Hirschberg in the same year used 20 per cent chocolate gelatin agar; Porterfield in 1944 reported the use of Bacto proteose No. 3 with hemoglobin and Bacto supplement A; and Higgenbotham in 1944 advocated the use of 0.2 per cent KNO₃ and shipment in thermos jugs with ice or dry ice. All of these investigators reported better results with cultures than with smears and better results with immediate than with delayed platings.

Russell Stein of the New Jersey State Department of Health in July, 1946, found from questionnaires returned from 44 state health department laboratories that 8 such laboratories offered no routine gonococcus culture service, 27 limited their service to local areas close to their laboratories, and that 10 offered a state-wide service with transportation media. Five of these states used Cox's medium, two used Hirschberg, one used McLeod's agar slants, one used horse plasma hemoglobin agar, and one used Buck's medium. Very few

of the directors of these laboratories felt that their methods were efficient but all agreed that transported cultures, no matter how poor, are superior to smears. This report was accompanied by an exhibit of the outfits distributed by the various states for this purpose.

Dr. Hirschberg then reviewed the experience of the North Carolina State Laboratory with the use of transportation media. She pointed out that while better media may be developed in the future, the present medium has been used in the examination of over 3,500 specimens and has yielded a substantial number of positive cultures from cases that were negative by microscopic examination of smears. Yeast extract is a good source of enrichment nutrients but crystal violet inhibits the growth of many strains of gonococci. Nile blue A which is used in Hirschberg medium does not inhibit the gonococcus but probably does not aid very much in holding down contamination. A good laboratory worker near the clinic or physician's office can isolate the gonococcus by direct culture of specimens from female patients three times as frequently as it can be demonstrated by microscopic smear examinations, and approximately twice as frequently in specimens from males. Transported cultures do not give such high ratios because temperature, food supply, drug therapy, local treatment, and the peculiar habits of the organism itself all interfere with the viability of the gonococcus during transportation. A series of duplicate specimens, half of which were incubated immediately, and half transported by auto in sealed jars for an hour before incubation, showed a drop of 15 per cent in the number of positives. Isolations from Negro and white patients did not differ markedly. Classification by purpose of examination showed 26 per cent positives in specimens for diagnosis, 24 per cent in contact specimens, and 20 per cent in

treatment control specimens. Of 460 routine smear and culture specimens sent by mail, 26 were positive by both methods, 33 by smear alone, and 54 by culture alone. Because New York State Laboratories, using the same medium prepared at a higher temperature and containing more blood, seemed to be getting better results; some comparative series were run with that medium but the difference seems to be accounted for chiefly by the fact that in New York physicians collected a very much larger percentage of the specimens. Occasional positive findings on one but not the other medium emphasize the fact that the more types of media are used the more positive isolations may be expected. At the present time the North Carolina laboratories are using a medium prepared by the original formula for transportation purposes but are using 10 per cent blood in medium prepared at 80°C. for plating.

Marion B. Coleman presented the experience of the New York State Division of Laboratories and Research with transportation media and methods essentially those of Hirschberg. Over a 27 month period, approximately 1,400 specimens from female patients were examined. Gonococci were isolated from 12.6 per cent and were found by microscopic examination in 7.8 per cent. Of the total number of specimens showing gonococci 20 per cent were missed by the culture method and 50 per cent by the microscopic method. In a relatively small series of 100 specimens from males the findings were in sharp contrast, gonococci being demonstrated in 36 per cent by microscopic examination and in 22 per cent by culture. During the same period a series of 711 triplicate specimens were collected from female patients in a local clinic; one swab was used immediately for direct inoculation of a plate which was incubated within 3 hours; a duplicate swab was stored in Hirschberg medium at room temperature

overnight and plates were inoculated the next day; while the third swab was used to prepare films on slides. Gonococci were isolated from 23.4 per cent and found microscopically in only 9 per cent. Direct plating yielded gonococci in 22.3 per cent and delayed plating in 18.7 per cent. It was concluded that reliance should not be placed on either microscopic or cultural examinations alone; both procedures are desirable.

Martha Morrison, in the absence of Dr. Charles M. Carpenter, presented a report on an improved reagent for the oxidase test. The oxalate salt of *p*-aminodimethylaniline has proved superior to the monohydrochloride salt previously recommended, being more stable and less likely to yield cloudy and highly colored solutions. Six months' storage in amber colored bottles showed no visible change in the dry oxalate salt, whereas the monohydrochloride showed pronounced darkening; 1.0 per cent aqueous solutions have greater clarity and show less precipitation on standing, colorimeter tests indicating that the oxalate solution needed to stand 72 hours in order to give a reading equivalent to the 24 hour reading of the monohydrochloride. A slight disadvantage of the oxalate is that it goes into solution somewhat more slowly, but this can be overcome by gentle heating.

Dr. Thomas H. Weller, the final speaker on the panel, presented a comparative study of media for the primary

isolation of the gonococcus.* Cervical and urethral swabbings collected from 815 venereal disease clinic patients served as the test material. Each specimen was suspended in proteose-peptone broth and thoroughly mixed; a drop of the suspension was then placed on plates of each of five media and spread over the surface with a wire loop. A modified Peizer medium, using human red cells and plasma, detected the greatest number of positives, 96 per cent; while Mueller-Hinton media, both freshly prepared and dehydrated (Difco), detected 90 per cent; 74 per cent of the known positives grew on Bacto proteose No. 3 agar with Bacto-hemoglobin and 72 per cent on the same medium with Bacto yeast supplement A. No difference was observed between the freshly prepared and dehydrated Mueller-Hinton media, and the speaker suggested its use in laboratories where limited facilities necessitate the employment of a dehydrated medium.

The discussion was brought to a conclusion with the statement of the panel leader, Dr. Justina Hill, that the morning's discussion had certainly shown how little was known about several aspects of gonococcus culture work and how great was the need for further study.

THE AMERICAN PUBLIC HEALTH ASSOCIATION

IN climbing a mountain, there are moments when one has surmounted an awkward cliff and pauses for a moment to look back and survey the ground gained as a source of satisfaction and an encouragement for what may be the even greater challenges which lie ahead. Such a moment is the celebration of the 75th anniversary of the American Public Health Association at Atlantic City last month.

The retrospect is of particular interest in this case, since the history of our Association is, in essence, the history of perhaps the most significant social movement of modern times. It was founded at the dawn of a new era, the era in which—for the first time in human history—the life span of the human animal ceased to be a plaything of Lachesis and became a factor largely under the control of the human will; when, in the words of Hermann M. Biggs, it became clear that “within natural limitations, a community can determine its own death rate.”

What was the status of “public health” seventy-five years ago? We had local boards of health in a number of our seaboard cities, dating back to the yellow fever epidemics of the last decade of the Eighteenth Century; but their weapons were limited to the crudest and most empirical procedures of sanitation and quarantine. Chadwick’s epoch-making report on *The Sanitary Condition of the Laboring Population of Great Britain* had, however, been published in 1842; and the even more far-sighted program of Shattuck (probably the most remarkable single document in the history of public health), his Report on the Sanitary Condition of Massachusetts, in 1850. Studies by Panum on measles (1847), by Snow on cholera (1849), and by Budd on typhoid fever (1859) had laid the foundation for modern scientific epidemiology. The anthrax bacillus had been seen by Davaine in 1850; Pasteur, between 1857 and 1865 had established the germ theory of fermentation and the doctrine of biogenesis, and Lister in 1867 had introduced antiseptic surgery. Massachusetts had established the first state board of health in 1869; and California and Virginia had followed suit in 1871, the same year in which the Local Government Board began its work in England. The foundation had thus been well and truly laid; but the construction of the building had not yet been begun. The discovery of controlled immunization (except in the case of smallpox) had yet to wait for the studies of Pasteur in

1880-1881; the discovery of the tubercle bacillus was to come only in 1882, and that of the diphtheria bacillus in 1884.

It was then a bold and creative vision which animated nine physicians¹ and one architect² to meet in New York City on April 18, 1872, and decide on the establishment of a national sanitary association. At this meeting a committee on permanent organization was appointed under the chairmanship of Stephen Smith; and on September 12 of the same year the American Public Health Association was formally organized at Long Branch, N. J., a constitution was adopted and Stephen Smith named as our first president. The objects of the Association were: "the advancement of sanitary science and the promotion of organizations and measures for the practical application of public hygiene"; and members (elected by two-thirds of the members present at an annual meeting, after recommendation by a majority of the Executive Committee) must be "selected with special reference to their acknowledged interest in, or devotion to, sanitary studies and allied sciences and to the practical application of the same."

It is of interest to note that the *New York Times* of September 17, 1872, in a discussion of "Minor Topics" on its editorial page made the following pertinent comment:

"We trust the American Health Association will prove worthy of its title, and of the formidable list of committees to which the leading subjects which it undertakes to investigate have been referred. There is a vast unoccupied field awaiting the action of such a society, and the many eminent names which appear among its members must secure, under proper organization, the obtaining of some very valuable results. Sanitary science, considered either in its statistical or other aspects, is but in its infancy among us, and there is certainly nothing more systematically neglected in our great cities than the most rudimentary and obvious of sanitary laws. We hope that the Association will direct its attention to the educating of public sentiment as well as to the furnishing of scientific data."

The first two meetings of the Association for the formal presentation of papers were held in the spring and fall of 1873; and the quality of these contributions³ was extraordinarily high. Stephen Smith made a reasoned and impassioned plea for increased longevity. He said, in relation to the vital statistics of the time, "Of the children born, what vast percentages never see the anniversary of their birth? What other large percentage dies within five years? How few, comparatively, reach the age of ten? At twenty the generation has dwindled to an insignificant minority, and at thirty-three to forty-five it disappears altogether."

Against this picture—not very much exaggerated so far as our great cities were concerned—he sets the century mark as a normal span for human life.

Francis A. Walker, then Superintendent of the Census, gave an extraordinary analysis of the relation of race and nationality to mortality in the United States which could well be used as a background by present-day students in this field. F. A. P. Barnard, President of "Columbia College" presented a thoughtful and open-minded analysis of current evidence in regard to the new germ theory of disease. Andrew D. White, President of Cornell, opened up the topic of "Sanitary Science in Its Relation to Public Instruction." Carl Pfeiffer discussed the "health principles of architecture." Austin Flint described the epidemic at North Boston, N. Y., in 1843, clearly traced to a polluted well, the first convincing example of this phenomenon upon our continent. Smallpox, cholera, and yellow fever, of course, received much attention. In the field of practical health administration, Elisha Harris presented a very sound review of the principles of "state

and local sanitary organization," and John M. Toner anticipated the work of the Committee on Administrative Practice with data obtained by a questionnaire on the administrative set-up and vital statistics procedures (including some salary scales) of 137 state and local boards of health in the United States. This subject was set up as a continuing activity of the Association through the presentation in 1875 of the report of a Committee on the Plan for a "Systematic Sanitary Survey of the United States," which included a schedule of inquiries running to more than 500 specific questions. At the same session⁴ Dorman B. Eaton, whose framing of the health laws of New York City is the basis of all our public health powers of today, presented an analysis of the political principles of health legislation which is still vital and inspiring in 1947.

The history of the Association (and of public health in general) from 1872 to 1921 has been admirably reviewed in a volume edited by M. P. Ravenel⁵; and in 1972 a second volume of this history should be compiled. Here, we can mark only the high points of the story. During the first quarter-century of the life of the Association, the annual meetings and the annually printed "Reports and Papers" essentially constituted its life history; and these volumes form fascinating reading. Eloquent laudations of Hygeia were not lacking; and we must not be surprised to find discussions of the influence of forests on health and proposals for the disinfection of sewers by ozone. We find also sound judgment and broad vision, which included such urgent present-day problems as housing (Stephen Smith called the home "the unit of sanitary administration"), industrial health, railway sanitation, and the like.

One cannot take one of these old volumes from the shelf without finding passages which are prescient and inspiring; and many a valuable doctoral dissertation could be based on a serious analysis of the trends of thought which they represent.

The gift by Henry Lomb of Rochester in 1884 of \$2,000 to be awarded for essays on certain specified topics (which included housing and nutrition, school hygiene and occupational hygiene) produced a crop of particularly significant papers in 1885.

By 1890, the membership of the Association had grown to over 500 and it was rated as "the largest and most influential organization in the world in shaping public health opinions." Most significant of all was the fact that this Association, conceived in New York City, and made national in scope in New Jersey, became international with the invitation to Canadian health workers to join in 1884. In 1892, Mexican health authorities took similar action and in 1902 Cuba followed suit. Our Association represents the public health movement not only in the United States but in the whole of the North American continent. Four flags are displayed on our platform; and representatives of Canada, Cuba, and Mexico have played a leading rôle in our program and in our organization as a whole.

Perhaps the most important step in the history of the Association (after the foundation of the Association itself in 1872) was the creation of its first specialized section, the Laboratory Section, in 1899. A series of preliminary conferences and committees initiated by Wyatt Johnston between 1894 and 1899 led to this happy result. Nearly one hundred members enrolled in the Section at once, of whom about half were new members of the Association. We are now, in the history of the Association, well within the limits of personal memory; and the writer can clearly recall the extraordinary influence of the Laboratory Section in bringing the methods and the attitudes of exact science into its deliberations.

This Section was the vital growing-point of the A.P.H.A. in the first decade of the present century. The precedent thus set was followed in other fields at the end of this demonstration period and thereafter, as the chronological list of our present Sections indicates:

1899	Laboratory Section	1921	Maternal and Child Health
1908	Health Officers	1922	Public Health Education
1908	Vital Statistics	1923	Public Health Nursing
1911	Engineering	1929	Epidemiology
1914	Industrial Hygiene	1942	School Health
1917	Food and Nutrition	1943	Dental Health

Thus, when the Association held its Fifty Year Jubilee in 1921, Stephen Smith who—at the age of 99—gave an address, could look back with pride on the edifice whose cornerstone he had laid. Already we had sections representing expertness in seven different specialized fields of public health (with five more to come). Increasingly these sections have become the life blood of the Association. The program of our annual meeting is a section program, with a dozen addresses at general and special sessions as frosting on the cake. The activities of the members of these sections furnish the advancing knowledge on which our program is based; and it is of incalculable importance that through the Association itself they are united in a profession conscious of its singleness of purpose and devoted to the general cause of public health.

In connection with the development of all the activities of the Association its regular printed publications have played an important rôle. For the first forty years of its history it published the annual volumes of *Reports and Papers*, to which reference had been made in a preceding paragraph. Volumes I to XXXIII of this series covered the annual meetings from 1873 to 1907. Volumes XXXIV and XXXV (1908 and 1909) were also printed in the *American Journal of Public Hygiene*. This was a publication with its own distinguished history, having been founded in 1890 as the *Journal of the Massachusetts Association of Boards of Health*. This *Journal* became the *American Journal of Public Hygiene* in 1904; and in 1908 became also the official organ of the American Public Health Association Laboratory Section. In 1911, its name was changed to the *American Journal of Public Health* and this *Journal* has since superseded the *Reports and Papers* which were no longer published after 1912. B. R. Rickards, Livingston Farrand (1912), S. M. Gunn (1914), A. W. Hedrich (1918), M. P. Ravenel (1924), and H. S. Mustard (1941) have successively guided the fortunes of the *Journal*, and a very special debt is due to Ravenel for his 17 years of devoted editorship.⁵ The names of Henry F. Vaughan and Homer N. Calver must be mentioned appreciatively in connection with the *Journal*. They served on a committee appointed by the Executive Board in 1923 to edit the *Journal* with Dr. Vaughan as Chairman.

In early years the office of the Association and the editorship of the *Journal* were identified in the same person (Rickards, Gunn, Hedrich). It was only in 1921 that the offices of the Association were moved to New York City in proximity to the other associations which made up the National Health Council; and only in 1923 that a full-time General Secretary without major editorial responsibility was appointed (H. N. Calver). After a brief interim, R. M. Atwater was appointed Executive Secretary in 1935, and for 12 years he has given us leadership so wise and so courageous, so human, so patient, and so farseeing that the recognition which he received at Atlantic City last month falls far short of his

desserts. The Association has been fortunate in having many devoted workers on its staff over the years; among them at the present time are five who have each given twelve years or more of top-grade service—Mrs. W. R. Walsh, whose efficiency and charm are central in all headquarters affairs, Miss Jeanne Bickel as accountant, Miss Edith Boyd as Associate Secretary of the Committee on Administrative Practice, Mrs. Augusta Jay as Editorial Associate, and Miss Elsie Siemer as Membership Secretary.

From a purely administrative standpoint, the year 1922 will always be memorable on account of the new Constitution then adopted. This document gave the Association a method of electing its Governing Council which is admirable and—so far as we are aware—unique. The make-up of this Council which includes three classes, officers of the Sections, representatives of local branches, and members-at-large elected by written ballot at the annual meeting, insures the broadest and most responsible representation of all important elements; and is absolutely fool-proof against any form of political manipulation. The second important provision of this Constitution was the creation of Fellowship grade which leaves the educational opportunities of the Association open to all who are interested in public health but maintains its direction in the hands of qualified professional experts. Under this plan the Association has shown phenomenal growth, from less than 3,000 members in 1923 to 11,382 members in October, 1947. Of these, 1,792 were Fellows. In the same period, the budget of the Association rose from less than \$100,000 to approximately \$350,000.

Development at the periphery has been equally rapid. We have now 27 local affiliated state (or regional) societies (including Cuba and Puerto Rico). In 1928 the Western Branch was established to hold regional meetings, representing wider areas at a distance from the nearest Association membership; and a similar Southern Branch was formed in 1932. In 1943 an annual tour of speakers, representing the Association, to address a series of special meetings in the Western States was inaugurated and has been continued with notable success.

To turn now from problems of organization to concrete achievement, we may set in the first place, historically, the development of standard procedures in the laboratory field. One of the first steps taken by the newly-formed Laboratory Section at the beginning of the century was the development of sound and uniform procedures for the examination of water and milk. The first edition of *Standard Methods for the Examination of Water and Sewage* appeared in 1905, preceded by six reports; that on the examination of dairy products, in 1910. It happens that in the present year (1947) both of these important committees have completed the Ninth Editions of their standard procedures.⁶ The value of these reports in developing sound scientific knowledge and securing uniformity of official practice has been simply incalculable and their influence has been world-wide.

The importance of activities of this type was so evident that, in 1930, an overall Committee on Research and Standards was set up as one of the permanent Standing Committees of the Association under the successive chairmanships of Abel Wolman, L. R. Thompson, K. F. Maxcy, and Thomas Francis. An exhaustive monograph, *Diagnostic Procedures and Reagents*, first issued in 1941, is one of the most important recent contributions along this line.

In the area of epidemiology a similarly significant achievement has been the preparation (under the inspired leadership of Haven Emerson) of a series of reports on the *Control of Communicable Diseases*. These reports (1917, 1926, 1935, 1940, 1945) have given us a tabulation of the most important known facts as to the etiology of 72 different communicable diseases, with clear indication of

the administrative methods of recognition, reporting, isolation, and quarantine necessary for their control. These procedures are rapidly being adopted by our various states. The current report was translated into Arabic, French, Italian, Portuguese and Spanish under the Office of War Information. It has been considered for official adoption by China, Canada, the United Kingdom, and various Pan-American Republics.⁷

The Vital Statistics Section has rendered similar—if less dramatic—service in promoting soundness and uniformity of statistical procedures in the field of public health. Its reports have been accepted as authoritative in this country and have had an important influence on the preparation of standard tables of mortality and morbidity on an international scale.

The establishment of the Committee on Administrative Practice in 1920, (made a permanent Standing Committee in 1926) may perhaps be considered to mark a third significant stage in the development of the American Public Health Association. During the Nineteenth Century, as we have seen, its services were rendered mainly through the rather general stimulation of its annual meetings. The establishment of sections with their reports on standard methods and the development of the *Journal* ushered in a phase in which invaluable contributions were made in the evaluation of sound procedures in the diverse special fields of public health. The C.A.P. initiated a vigorous revival of activities concerned with the balance and administrative efficiency of the public health program as a whole, such as Harris and Billings had visualized in the 1870's.

The inspiration of this committee was the pioneer work of C. V. Chapin, who had for years emphasized the responsibility of the health officer for getting maximum results from each health dollar and who published the first comprehensive survey of the work of our state health departments in 1915. The committee has operated under the successive chairmanships of C.-E. A. Winslow (1920–1935), E. L. Bishop (1936–1941), Henry F. Vaughan (1942–1943), and W. L. Halverson (1944). Watson S. Rankin was its first full-time Field Secretary (1923–1925) and W. Frank Walker (1925–1931) its second, each making outstanding contributions. The services of Carl E. Buck as Field Director for 16 years has been of supreme value.⁸

The five major objectives of the C.A.P. have been stated succinctly as follows:

1. Secure authentic information as to the actual practice of American communities in the field of health organization.
2. Utilize the information in the form of a typical community health program which might be set up as a norm or as a general guide to be used by any community which aspires to provide adequate health protection for its citizens.
3. Devise a method by which the health officer may appraise the results obtained by his program.
4. Make results of surveys, standards of administrative practice, and appraisal procedures directly available to health officers.
5. Secure popular support for public health programs by using the appraisal scheme to arouse local interest in health achievement.

Its first step was to prepare—on the basis of preliminary surveys of nearly 200 cities—an appraisal form for the objective recording (so far as possible in quantitative terms) of the actual performance of a given community; and the results of this study were crystallized in the volume prepared by I. V. Hiscock on *Community Health Organization*. In 1929, the committee began active stimulation of sound administrative practice through the Health Conservation Contest and the

National Health Honor Roll. In 1943, this effective promotional device had fulfilled its purpose and the committee replaced it by the application of Health Practice Studies as a basis for a National Reporting Area. The competitive element is thus subordinated, and a basis laid for continuing uniform comparative recording of actual results obtained, carried out through the medium of the state health administrations. Louis I. Dublin has stated "I have no hesitation whatever in saying that the appraisal methods developed by the committee have truly revolutionized public health practice in the United States and in some other countries as well."

One of the most important revelations of the committee's studies was the deplorable lack of organized health services in the rural areas of the United States and Canada. In 1942 the Association adopted a resolution demanding complete coverage with full-time health service for both countries; and a subcommittee on Local Health Units was appointed (under the chairmanship of Haven Emerson). In 1945 a bold and creative report was published on *Local Health Units for the Nation*. The committee has prepared a detailed outline showing how the entire United States could be covered by 1,200 local administrative units, each under the direction of a full-time trained medical health officer assisted by the necessary sanitary, nursing, and other personnel. The program proposed is being actively promoted by institutes in various strategic areas; and the progress made in many states is such as to encourage the hope that the ideals set forth should be within our grasp in the next decade.

Another most fruitful new avenue of usefulness was opened up in 1932 by the establishment of the Committee on Professional Education, as one of the three major Standing Committees of the Association concerned with constructive service in the public health field, alongside of the Committee on Research and Standards and the Committee on Administrative Practice. No administrative machinery, however perfect, can function without the right personnel; and, in a field of such diverse specialization as ours, the problem is one of great complexity. Under the chairmanship of W. L. Leathers and W. P. Shepard, this committee has accomplished herculean tasks. It has formulated detailed and precise statements defining the qualifications for health officers and for fourteen different types of specialists in various fields of public health. It set up in 1940 a Merit System Unit in the office of the Association which has undertaken the preparation of examinations to be used by states and cities in the selection of professional public health personnel. The unit has combined the judgment of experts in the various specialties of public health with tested psychological techniques and has prepared, on request, 294 examinations in various fields (including 135 for nurses, 76 for laboratory workers, 53 for engineers and sanitarians, 20 for administrators). These examinations have received an extraordinarily favorable reception.

In 1945 the committee established a program for the accreditation of universities offering the degrees of M.P.H. and Dr.P.H., including the formulation of standards and periodic inspection, and eleven such universities have been formally accredited for this purpose. Since 1945 a useful Vocational Counselling and Placement Service has been provided at headquarters; and the committee is carrying on an active campaign for increasing the inadequate salaries of various types of public health personnel.

The Association has not permitted its proper preoccupation with the improvement of what are now recognized as parts of the standard health program to blind it to the widening health challenges of the future. The appointment of a Com-

mittee on the Hygiene of Housing in 1936 has led to the development of a procedure for the objective and quantitative appraisal of substandard housing which has been applied by health officers from Portland, Maine, to Los Angeles as well as in Hawaii and the Canal Zone; and systematic supervision of dwellings is likely to become a regular function of progressive health departments. The committee is now preparing a series of reports on standards for the housing of the future; and is analyzing the legal relationships of the health department to housing and preparing the basis for a standard housing code.

The most difficult and most challenging problems of public health in the future are those related to medical care. The aging of the population, with the inevitable relative increase in diseases of later life, has brought this problem before us with compelling force; and earlier attempts to separate "preventive" from "curative" medicine have proved obviously unworkable. A subcommittee of the C.A.P. on Organized Care of the Sick had been in existence from 1921 to 1935. In 1937, a new committee was appointed to study the public health aspects of medical care and to cooperate with various associations "in extending public health work to meet modern needs." In 1943, after a period of intensive study and discussion, this group, whose name had in 1943 been changed to Subcommittee on Medical Care, with Dr. Joseph W. Mountin of the Public Health Service as chairman, presented to the parent committee and, in turn, to the Governing Council of the Association "a set of principles expressing the desirable content of a comprehensive program of medical care, the methods of its administration, and the part which public health agencies should take in its operation." As a result, Medical Care in a National Health Program, an Official Statement of the American Public Health Association, was adopted by the Governing Council on October 4, 1944.⁹ This report recognized the vital need for a national program of medical care that should make available to the entire population all essential preventive, diagnostic, and curative services of the highest standard, and rendered under conditions satisfactory both to the public and to the medical professions. It pointed out that the public health agencies—federal, state, and local—must obviously carry a major responsibility in administering any comprehensive program of medical care. The Association, by this action, aligned itself with the forces of constructive progress in this field and is in position to render the greatest service in guiding such progress along sound professional lines.

Since 1946 the Subcommittee on Medical Care has had the services of a small, but expert staff; and has recently participated in a joint study of the principles which should govern the care of the chronically ill which has received the joint approval of the American Hospital Association, the American Medical Association, the American Public Health Association, and the American Public Welfare Association.¹⁰

Two events of general Association history during the past quarter-century have been the establishment of the William T. Sedgwick Memorial Medal Award in 1924, and of the Albert B. and Mary Lasker Awards in 1945. These provisions for the recognition of distinguished service to the cause of public health have proved (as did the Lomb Prizes in an earlier day) of national significance; and the actual awards add greatly to the color of our annual meetings.

This highly condensed review of the past history of the A.P.H.A. may well give us cause for gratification. We owe a deep debt to the founders of 1872 and to the far-sighted leadership which has carried our standard onward to even greater achievement. The list of past presidents (reproduced in this issue of the

Journal) is in itself an inspiration. Stephen Smith, John S. Billings, Henry P. Walcott, G. M. Sternberg, Frederic Montizambert, Samuel H. Durgin, Eduardo Liceaga, Peter H. Bryce, Benjamin Lee, Walter Wyman, Carlos J. Finlay, F. F. Westbrook, J. N. Hurty, Rudolph Hering, W. T. Sedgwick, C. J. Hastings, Lee K. Frankel, M. P. Ravenel, W. H. Park, George W. Fuller. Here is an honor roll of the finest public health leadership in Canada and Cuba and Mexico and the United States—health administrators, laboratory workers, engineers, university teachers, great public servants. There are a dozen more in later years—of the same distinction—who are still active in the councils of the Association.

The founding fathers set our goal at a human life span of one hundred years; and Stephen Smith, in his own person attained this goal. The century-mark has not yet become the average expectation of life; but in 75 years we have made outstanding progress toward this goal. In 1871 the general death rate of New York City was 28.3; in 1946 it was 10.4—a decrease of 63 per cent. In 1870 Francis A. Walker estimated the average expectation of life at birth in the United States at 39 years; in 1946, it is 65 years—an increase of 67 per cent.

These figures are familiar and we take them as a matter of course. Perhaps the most fundamental task of public education is to make people realize the obvious—to grasp its actual meaning in human terms, with their inner consciousness and not merely with their eyes and ears. If you could stand by the bedside of a man dying at 39 and tell him he could live for 26 years more, that would be recognized as a miracle. Such a miracle has actually happened to the average man in the last seventy-five years. There is no comparable phenomenon in the history of the human race. Wars and depressions are minor and temporary compared with this achievement. It has recently been pointed out that our casualties in World War II (300,000) were more than balanced by reductions in the civilian death rate during the same period. The decline in maternal and infant mortality rates during these years, alone, correspond to a saving of 175,000 lives.¹¹

We may well be proud of the past. To the young men and women who may read this editorial, we say "Carry On." The next quarter-century is in your hands.

* Deceased

THE VICTORY OVER MATERNAL MORTALITY

ONE of the most striking achievements in the whole realm of vital statistics is the reduction in the maternal mortality of the United States during the past decade. Between 1915 and 1933, this rate fluctuated between 6 and 8 maternal deaths per 1,000 live births (except for an increase to about 9 in 1918). Since 1933, there has been a steady and continuous decline to a trifle over 2 such deaths per 1,000 live births in 1944 and 1945.

This is a really extraordinary phenomenon. It is difficult to think of any really comparable instance, in which the mortality rate from any particular disease or group of diseases in the United States has been cut by two-thirds in one decade.

Furthermore, it seems difficult to explain that decline on the basis of any fundamental change in general public health policies or techniques. The Children's Bureau and the state and local health departments and the nursing associations and other voluntary agencies have played their part in the happy result; but these agencies have progressed steadily and did not introduce any sudden change of program ten years ago. For so sharp a break in trend, we must look for some new factor.

What did happen in the thirties was the conduct of a series of studies by the

New York Academy of Medicine¹ and by other state and local medical societies of the causes of maternal mortality in routine family and institutional practice; and these studies led to clear and courageous conclusions in regard to the considerable volume of maternal deaths due to faulty obstetrical practice and, particularly, to unnecessary recourse to instrumental delivery. These reports brought about amazingly prompt reform in such practice; and it seems probable that this factor—the one new factor which entered the picture ten years ago—must be given major credit for the results of the past decade. If such be the case, we have here a striking example of an outstanding public health success accomplished largely by the medical profession itself through the leadership of its own professional organizations.

Clearing House on Public Health

Salary Information

EXECUTIVE SALARIES
13 LARGE CITIES

Earl Smith, M.D., Medical Director of the Communicable Disease Control Section of the St. Louis City Division of Health, furnishes the following material based on a questionnaire study of city health department salaries at the executive level in 13 of the largest cities

in the United States. By way of caution he says, "It should be emphasized that comparison of an individual city with the average will only indicate whether it is out of line with usual practices and suggest the need for further analysis of operations." It should further be noted that this is a tabulation of maximum salaries.

PUBLIC HEALTH EPIDEMIOLOGIST
SALARIES

Franklin H. Top, M.D., Secretary of the Epidemiology Section of the Association, reports recent action of the Epidemiology Section Council on salaries of epidemiologists as follows:

Cognizant of the difficulties involved in suggesting or determining a salary schedule for epidemiologists which would fit all health units—local, state, and federal—the Epidemiology Section suggests the following broad policy on salaries, patterned after the proposed statement by the Executive Board on salaries of public health administrators:

A. Physicians with an M.D. degree from an approved medical school followed by internship plus a master's degree in public health, not less than 2 years of full-time experience under supervision, should receive a minimum annual starting salary which is not more than one step below the minimum annual starting salary of the administrator, namely \$1,000 under the minimum annual starting salary of \$8,500 suggested for public health administrators with regular increments to a salary level of at least \$10,000. Where there is a marked difference between an administrator and/or his deputy and

the remaining personnel, the minimum starting salary should be not less than \$8,000.

B. Physicians with an M.D. degree from an approved medical school, followed by internship and 2 or more years of successful full-time experience, but without graduate training, should receive an annual starting salary which is *not more* than two steps below the minimum starting salary of public health administrators; namely, \$2,000 under the minimum annual starting salary of \$8,500 suggested for public health administrators with regular increments, to a salary level of at least \$8,000. Where there is a marked difference between an administrator and/or his deputy and the remaining personnel, the minimum starting salary should not be less than \$7,000.

C. In the event that a physician lacks the graduate training but has had a particular formal training such as several years on a communicable disease service or success in an allied field together with a number of years of full-time experience in a well organized health agency, he might be considered for a starting salary between the levels of Categories A and B with the suggestion that academic training leading to the degree of Master of Public Health be obtained at the earliest opportunity.

LETTERS TO THE EDITOR

TO THE EDITOR:

In reading the publication by Milton I. Levine in the *American Journal of Public Health*, 1947, vol. 37, page 1089, I note several errors which I would greatly appreciate having corrected, especially in view of the wide circulation of the *Journal*. On page 1092 the studies were undertaken on four different reservations and in southeastern Alaska instead of "8 different reservations." On page 1093 the quotation "It is, of course, not possible to be certain that no bias was unintentionally introduced," refers not as Dr. Levine states to our methods of selection but to an evaluation of the results. On page 1095, Table 7, the percentage of positive tuberculin reactions one year after vaccination was not 56 but 93.3 (*Public Health Reports*, 1946, vol. 61, page 810).

See also the following publications:

"BCG Vaccine," *Amer. Rev. Tuberc.*, 1940, vol. 42, page 661.

"The Specificity and Sensitivity of the Tuberculin Reaction Following Vaccination with BCG." *Amer. J. Hygiene*, 1941, vol. 33, page 45.

"Tuberculosis Control Among the North American Indians." *Amer. Rev. Tuberc.*, 1942, vol. 45, page 49.

I would greatly appreciate your making the above corrections in the near future.

JOSEPH D. ARONSON, M.D.
Assoc. Prof. Bacteriology,
Henry Phipps Institute,
University of Pennsylvania

September 15, 1947

TO THE EDITOR:

This is to compliment you upon the excellent article by Bleecker Marquette in the August issue of the *American Journal of Public Health* and also upon the fine editorial in the same issue. I thought you both did a fine piece of work in preparing them.

Since so many people in Washington live in rural areas we are particularly concerned with the development of county health councils, a subject of which Mr. Marquette was not overly optimistic. We have four at present in the state which are really county-wide in scope, and two others which are county-wide in name only. By the

end of the month we hope to have off the press a brief pamphlet entitled "Health Councils for Washington." which deals with the rural county health council. I will send you a copy when it is available.

Undoubtedly the development of health councils will be slow, just as full coverage with full-time county health departments, and your support for the idea in the *Journal* will certainly help.

HOWARD W. LUNDY, Dr.P.H.
Head, Health Education Section,
State Department of Health,
Seattle, Wash.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

An Appraisal Method for Measuring the Quality of Housing. Part II. Appraisal of Dwelling Conditions. *New York: American Public Health Association*, 1946. 246 pp. Price, \$5.00.

The Committee on the Hygiene of Housing presents Part II of a yardstick for health officers, housing officials, and planners, this contribution, prepared by Allan A. Twichell, being divided into three volumes: (a) survey director's manual, \$2.50; (b) field procedures, \$1.00; (c) office procedures, \$2.00. The broad purposes of a housing survey have been previously presented in Part I, *Nature and Uses of the Method*. A third part, in preparation, will deal with the appraisal of neighborhood environment.

As stated in a foreword by Rollo H. Britten, Chairman, Subcommittee on Appraisal of Residential Areas, these manuals are intended to facilitate a local survey to be undertaken in association with consulting service provided by the committee. It is hoped, however, that such service will encourage the maintenance of a continuous inventory of local housing conditions. The director's manual carries the reader through each detail of the survey, from the organization of the sponsoring community and the preparation of the survey staff, through a description of the appraisal items, to the collection of data, processing of records in the office, to final analyses and interpretations. Nothing has been left to the imagination of the student of survey methodology. Each detail has been presented in elementary school fashion, undoubtedly for the sake

of uniformity, understanding, and in order to serve as equipment for the surveyor of limited schooling. It will be interesting to note whether much of the text can be consolidated as more field experience is at hand. The manuals are well done and should prove useful tools for every health administrator and teacher interested in housing, and this should include every one of us. Appreciation is again due to Winslow and the members and able staff of his excellent committee. HENRY F. VAUGHAN

Microbial Antagonisms and Antibiotic Substances—By Selman A. Waksman. (2nd ed.) *New York: The Commonwealth Fund*, 1947; 415 pp. Price, \$4.00.

The need for a book like *Microbial Antagonisms and Antibiotic Substances* was well indicated when the first edition of this work went through two printings in the year that it appeared on the market. In this second revised and enlarged edition the table of contents is identical with that of the first edition.

The ecology of the microbic antagonisms native to soil and water is fully discussed in a manner that is logical, clear, and interesting. However, the book attempts to coordinate over a thousand references, and thus appears cumbersome, and in places is stilted and repetitious. Progress in this field is so rapid that almost any book on the subject would be in some respects obsolete at publication. The book can hardly be recommended for its discussions of the chemical and medical aspects of the subject. No reference is made to chemical methods employed for the deter-

mination of penicillin and streptomycin. Frequently references are used without much analysis. It is stated on page 204 that barium salt of penicillin is generally used when common knowledge recognizes barium salt as extremely toxic. On page 206, where the formulae of the penicillins are presented a little addition would give molecular weights from 312-350 instead of the weights 490-510 noted on page 207; the latter are early estimations from an outdated reference. On page 241 Dr. Waksman doubts that streptomycin could be inactivated by blocking a single group, the carbonyl group, in so large a molecule, while larger molecules are known to have been inactivated by merely reversing the direction of optical rotation to a plane of polarized light.

The book, however, contains much information of historical and current interest on antibiotic substances and microbic antagonists; its copious references date from 1863 to 1946. It will be profitably read by the scientific minded person interested in these topics. Experts will find the information useful if regarded critically, and others will be skillfully introduced into the field and brought up to date (1946).

K. F. MEYER

Nutrition in Industry—By Lionel Bradley Pett, Robert S. Goodhart, and David H. Blueloch, with an introduction by Frank G. Boudreau. Montreal: International Labour Office. *Studies and Reports*, No. 4, 1946. 177 pp. Price, \$1.50.

The International Labour Office which issues from time to time special reports on subjects which affect industry and labor has performed a real service by publishing in this book accounts of the steps taken in three countries (Great Britain, United States, and Canada) to safeguard the nutrition of industrial workers during the recent war.

The type of warfare of World War

II soon made it evident that the outcome would depend as much on the ability to produce and transport vast armaments as on operations in the field. This, in turn, demanded that the health, morale, efficiency, and welfare of industrial workers be maintained at an optimum. In this connection, all three governments developed active nutritional programs.

In addition to contributing to the maintenance of a high level of industrial production and the development of in-plant feeding organization, these programs helped to supply more precise information on the relation of diet and nutrition to health and working efficiency and to the nutritional status of the worker.

The benefits both as to health and to labor-management relationships of this wartime activity are so generally recognized by employer and labor that the provision of an opportunity to obtain meals at the place of employment is rapidly becoming an integral part of the pattern of American industrial society. This book summarizes the experience in this field to date. OTTO A. BERRY

School Health Problems. By Laurence B. Chenoweth, M.D., and Theodore K. Sellink, M.D. (3rd ed.), with an Outline on School Health Administration by Richard Arthur L. New York: F. S. Crofts & Co., Inc. 419 pp. Price, \$3.00.

This book was first published in 1937 "to acquaint students of education, teachers in service, and others interested, with the broad general field of health problems in schools." The second edition published in 1946 is almost identical with the first. The new treatments and new problems mentioned, are given in detail. There is only brief reference to Swander's work and then only in relation to the ability of teachers to identify children for medical help.

school nurse or physician. The Wetzel Grid also is inadequately discussed in the text, although a brief description of the technique is given in the appendix.

The chapters on growth are perhaps the best feature of the book. Five chapters dealing with growth and nutrition constitute about a quarter of the publication. A large bibliography accompanies most of the chapters. Unfortunately, many of the references are now more than twenty years old. If the authors would substitute for these older publications recent contributions of significance, the value of the book for new readers would be enhanced.

There is insufficient discussion of rheumatic fever. Some of the medical theory appears dated—for example, abscessed teeth are mentioned as an important factor in the development of heart disease and rheumatic fever. In a publication directed to non-medical workers, the glands of internal secretion are reviewed in too much technical detail and out of proportion to their importance as health problems in school children. The description of epilepsy is unfortunate and will tend to create a more pessimistic attitude among educators with respect to the education of these children.

Teachers, nurses, and others concerned with the school child have need for a volume which will orient them to the health problems of school children. *School Health Problems* helps but does not fully meet this need.

GEORGE M. WHEATLEY

Social Aspects of Public Housing: An Evaluation of North Carolina Experience — By Sanford Winston. Raleigh, N. C.: North Carolina Council of Housing Authorities, 1947. 44 pp.

This is the report of a sociological study of 194 white and 112 Negro families who have lived in public housing projects in one or another of 6 different North Carolina cities. All subsequently

moved to other homes. Data are presented on family size, occupations of husbands, education of householders, sanitary conditions of dwellings from and into which they moved, and social interests of the group.

It is evident that for this group of families, tenancy in public housing has raised their standard of living to such an extent that they have sought and obtained privately-owned quarters which are far superior to the slums whence they originated.

M. ALLEN POND

The Murine Type of Tubercle Bacillus. (The Vole Acid-Fast Bacillus)—By A. Q. Wells. With *Notes on the Morphology of Infection by the Vole Acid-Fast Bacillus*—By A. H. T. Robb-Smith. Medical Research Council Special Report Series. No. 259. New York: British Information Services, 1946, 48 pp. Price, \$.70.

A very complete survey of the knowledge to date concerning the vole acid-fast bacillus is contained in this report. A description is given of the disease as it occurs in voles and its similarity to tuberculosis.

Morphologically the bacillus is notably pleomorphic with the majority of the bacilli bent in various forms. It is strongly acid-fast and grows best on media without glycerine. Serologically it is indistinguishable from the human and bovine types. A tuberculin can be prepared from the vole bacillus which gives reactions in animals infected with the human or bovine tubercle bacilli, and animals infected with the vole bacillus show a sensitivity to human and bovine tuberculin.

The pathogenicity for various laboratory animals, such as the guinea pig, rabbit, white mouse, golden hamster, and other voles is given. When administered in large doses to laboratory animals it can produce progressive disease indistinguishable histologically from

that produced by the human and bovine types of tubercle bacillus. In view of this fact and its characteristic morphology, cultural needs, and pathogenicity, it must, therefore, be considered as a third mammalian type of tubercle bacillus.

Detailed description of experiments and protocols are given demonstrating increased resistance by vaccination of animals with the vole bacillus to subsequent infection with virulent tubercle bacillus. It is concluded that in man immunization with the vole bacillus has proved to be safe and the local reaction resulting is similar to that following BCG vaccination. Tuberculin allergy following vaccination in man with the vole bacillus is greater and occurs earlier than that following BCG vaccination. It has not so far been possible to evaluate the degree of resistance that can be induced in man.

A description is given by Robb-Smith of the lesions observed in relation to the number of organisms present in different tissues from naturally infected voles, as well as in experimentally infected rabbits, guinea pigs, and white mice. Lesions also produced in the vole by artificial infection with human and bovine type tubercle bacilli are described. Many illustrations accompany the descriptions.

The whole report is given in a conservative manner, which is convincing of the possible application of human vaccination with the vole bacillus. The need for further investigation in this phase is clearly indicated.

FLORENCE B. SEIBERT

Our Rural Communities — A Guidebook to Published Materials on Rural Problems — By Laverne Burchfield. Chicago: Public Administration Service, 1947. 201 pp. Price, \$2.50.

As its title indicates, this is a source book for those who are dealing with

any of the various aspects of rural social problems such as health, welfare, housing, land use, recreation, library service, etc. There is a general bibliography as well as a special bibliography following each of the 13 chapters.

The public health worker will be interested not only in the chapter on medical care and health services, but in the other chapters as well, because taken together, they give a bird's-eye view of the fact that no one of the problems is isolated. Land use, for example, is related to schools and health; local government is related to each of the problems.

The book is interesting for another reason. It originated in the work of a committee of the American Country Life Association following its 1944 conference on farm and rural life after the war. It is thus an illustration of the way in which a group saw its own need and met that need.

MARTHA LUGINBUHL

The Papworth Families: A 25 Years Survey— By E. M. Brieger. New York: Grune & Stratton, 1946. 674 pp. Price, \$12.00.

This book is a report of the dwellers in the Papworth Settlement, drawn up thirty years after the initiation of that experiment. It analyzes in considerable detail the history of the 142 families, and particularly of the 368 children of these families who were kept under constant supervision while at the settlement.

Although no case of active tuberculosis, and no case of active primary infiltration has been observed in the 108 children born at Papworth, Dr. Brieger admits there is no guarantee against exacerbations in later adult life.

The data are presented in numerous sub-divisions by place of birth of the children, by sputum of the original patient, by size of family, and other factors, all of which provide an invaluable epidemiological reference.

The book contains an interesting historical review of the beliefs held at various times as to the communicability of tuberculosis. The appendix, giving details of the case histories of all families, provides added data which many will value.

Environment, particularly as it affects security and prevention of exposure to massive infection, is, according to Dr. Brieger, the lesson in tuberculosis control taught by the Papworth experiment.

JAMES G. STONE

Standard Methods of the Division of Laboratories and Research of the New York State Department of Health—By Augustus B. Wadsworth, M.D. Baltimore: Williams & Wilkins, 1947. 990 pp. Price, \$10.00.

This storehouse of information of public health laboratory methods has been an essential reference book in public health laboratories since the publication of the first edition in 1927. In this third edition Dr. Augustus B. Wadsworth culminates a career of thirty-three years of noteworthy contributions to medicine and public health as Director of the laboratories of the New York State Department of Health and brings up to date the procedures and techniques developed during his one-third century as Director of that laboratory. The general format of past editions is retained. Through 75 chapters detailed descriptions are given of all techniques and procedures currently employed in the highly developed and efficient New York State laboratory system.

This edition contains numerous changes and additions. Noteworthy among these is the method for the preparation and use of the new cardiolipin antigen in the serodiagnosis of syphilis, which has been developed in the New York State laboratories since the publication of the second edition. A chapter is added on biologic assay,

and numerous changes and additions are to be found in other sections. The appendix provides excerpts from the *State Law and Sanitary Code* relating to laboratories and gives procedures for the submission of specimens. The importance of these latter details is well recognized by all workers in public health laboratories.

The book is well printed and is bound to withstand the hard usage of the laboratory. It is replete with bibliographical references that further enhance its value.

This edition should be available for ready reference in every public health laboratory. It will also be found to be of value to any public health workers who depend upon the laboratory for assistance in the solution of their problems.

MALCOLM H. MERRILL

Tuberculosis Nursing—By Grace M. Longhurst, R.N. (2nd. ed.) Philadelphia: Davis, 1947. 358 pp. Price, \$3.50.

This second edition of *Tuberculosis Nursing*—which has become a valuable nursing library item—has several new chapters as well as many timely revisions. One chapter titled "Patient Education" is especially helpful. It gives specific suggestions for teaching in relation to many of the factors involved in tuberculosis nursing; it suggests opportunities when this teaching will have its greatest value to the patient and/or his family and it hints of teaching aids which will supplement day-by-day teaching.

The chapters of Case Histories also suggest methods of approach to particular problems which are found repeatedly among tuberculous patients. The detail of "Method of handling the patient and his problem" could have been made more meaningful. A student might profit more from a detailed reporting of the actual, practical plan undertaken than by the statement that

"An appeal has been made to her superior intelligence" or that "a patient of this type needs to be reassured constantly."

In view of the fact that Miss Longhurst feels that nurses should be able to explain the "How, Why and When" of the disease, it seems unfortunate that clinical tuberculosis is not dealt with more fully. An intimate understanding of the qualitative classification of tuberculosis is important—as well as the quantitative classification—if the nurse is to do as intelligent and effective job as we expect. This kind of information would seem to be more vital than the many pages given over to the specifics of procedure and technique. Undeniably the nurse needs to be familiar with the principles of a safe technique but the institution in which she works will no doubt have established procedures.

The recommended readings and questions suggested for review at the end of each chapter are comprehensive and should be useful to the teacher or student of tuberculosis nursing.

ALINE LEMAT

Clinical Practice in Infectious Diseases—By E. H. R. Harries and M. Mitman. (3rd ed.). Written and printed in Great Britain. American Publishers: Baltimore. Williams & Wilkins, 1947. 679 pp. Price, \$4.50.

The authors of this excellent book are medical superintendents of English hospitals who have evidently had extensive clinical experience in the management of the various contagious diseases. Besides 8 introductory chapters on the general principles of infection and of diagnosis, and 4 concluding chapters on the management of infectious diseases under varying circumstances, there are 26 chapters discussing various of these diseases, but there are no accounts of such other contagious diseases as syphilis, gonorrhea, or

the common cold. In general the description of the maladies and of their complications, prevention, and treatment are concise, accurate, and up-to-date; and there are many helpful diagrams, charts, and tables, but no photographs—colored or otherwise—of the actual conditions. Many of the chapters have bibliographies appended but the titles of the references are not given, thereby losing much of the value of such bibliographies. There are a number of minor matters in which British custom and procedure evidently differ from American, but nothing of particular moment was found except the recommendation of codein and barbiturates for acute poliomyelitis—drugs which are contraindicated because of the danger of the patient's stopping breathing during artificially produced sleep. On the whole, the book can be very highly recommended, particularly to medical students.

PHILIP M. STIMSON

Manual for Sewage Plant Operators—By L. C. Billings, Editor-in-Chief. Austin: Texas Water Works Short School, 1946. 426 pp. Price \$3.50.

The Editor's Preface contains as good an explanatory statement as any in stating, "It (the *Manual*) represents an effort of the State Association to bring together practical knowledge and experience in such co-ordinated form as will serve as a text for instruction to those interested in the operation of sewage plants and sewerage systems." The non-technically trained, operational individual will find this volume particularly useful. Consideration of theory is held to a bare minimum. The *Manual* starts with a discussion of general characteristics and significance of sewage and progresses through the various factors involved in treatment. Technical terms, where used, are explained.

FRANCIS B. ELDER

Statistical Abstract of the United States, 1946—Compiled under the supervision of Morris H. Hansen, U. S. Department of Commerce, Bureau of the Census. Washington: U. S. Government Printing Office, 1946. 1,039 pp. Price, \$2.25.

This 67th annual edition of the *Statistical Abstract*, like previous editions, contains summary information from important statistical publications in the United States. Thirty-four sections of the volume deal with statistics of area, population, vital statistics, criminology, climate, military affairs, business and finance, industry (including agriculture), public works, transportation and communication, and foreign commerce. Because of the wide scope of the volume, information is largely restricted to data for the nation as a whole and for the states. The material is well annotated, however, so that the user of the *Abstract* can refer to original sources of data for additional detail. Public health personnel will find this volume useful not so much for vital statistics and population data (since they are more likely to use the primary sources for these subjects), but for the occasional use of statistics in other fields and for the "Bibliography of Sources of Statistical Data" at the

end of the volume. The *Abstract* is an important adjunct to the library of a statistician working in any field.

EILEEN W. JONES

Units in Personal Health and Human Relations — By Lillian L. Biester, William Griffiths, and N. O. Pearce, M.D. Minneapolis: Minnesota Press, 1947. 267 pp. Price, \$3.50.

Educators who believe that sex education should be part of education for living will welcome this volume. It was prepared as a guide to group discussion and contains basic facts for teachers which will enable them to present material on reproduction and its social factors adequately.

The authors suggest that the material should be integrated with other subjects such as science, home economics, and health education to obtain effectiveness and a wholesome approach.

Teacher training institutions might well use this book for group discussions for those who expect to be guides to youth. The weakness in teaching the subject at the present is the lack of teacher preparation.

References used are sound and the accompanying vocabularies are explained. It is a useful volume.

MARY P. CONNOLLY

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

AMERICA'S NEEDS AND RESOURCES. By J. Fred-eric Dewhurst. New York: Twentieth Century Fund, 1947. 812 pp. Price, \$5.00.

THE CARE AND TREATMENT OF THE ELDERLY AND INFIRM. Report of a Special Committee of the British Medical Association. London: British Medical Association, 1947. 28 pp. Price, \$15.

CALCIUM AND PHOSPHORUS IN FOODS AND NUTRITION. By Henry C. Sherman. New York: Columbia University Press, 1947. 176 pp. Price, \$2.75.

CONCISE CHEMICAL AND TECHNICAL DICTIONARY. Edited by H. Bennett. New York: Chemical Publishing Co., 1947. 1,055 pp. Price, \$10.00.

CITY FINANCES: 1945 (Cities Having Populations over 25,000). Prepared under the supervision of Allen D. Manvel. Washington, D. C.: Supt. of Documents, U. S. Gov. Ptg. Office, 1947. 258 pp. Price, \$1.25.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Diphtheria Can Be Eliminated, It Says Here—Diphtheria deaths continue to increase. New England cities had the worst record, those in the East South Central group of states the best.

ANON. Diphtheria Mortality in large Cities in the United States in 1946. *J.A.M.A.* 134, 18:1540 (Aug. 30), 1947.

Despite Skeptic's Opinion—This committee seems to have produced a thorough-going re-statement of the whole rabies control story. Probably the one finding that will stick in your crop is the assurance that earlier doubts about the efficacy of canine vaccines can now be laid to rest. The extreme ultra-violet irradiated vaccine really does the trick, they assure us. There are eleven recommendations for rabies control proposed by the committee.

ANON. Control of Rabies. *Pub. Health Rep.* 62, 34:1215 (Aug. 22), 1947.

Coöperative Planning Is Their Answer—Thumbing through the abstracts of eight viewpoints on the matter of school child health leaves the impression that the Canadian-USA border separates few differences in the overall administrative problems or in the usual community deficiencies in meeting them.

ARMYOT, G. F., *et al.* School Health Services. *Canad. Pub. Health J.* 38, 8:361 (Aug.), 1947.

The Need Is Indisputable—Milwaukee, Detroit, Los Angeles, and Baltimore Health Departments have made a stab at getting rid of sub-standard housing and substituting decent human dwelling places. Let's see; how

many American cities over 100,000 are there?

BOARD, L. M. The Local Health Department Program in Housing. *Pub. Health Rep.* 62, 37:1327 (Sept. 12), 1947.

Quote—The greatest event in English medicine, the birth of the National Health Service, has passed into history. Gestation was prolonged and often complicated, labor quick and uneventful, and now the baby grows apace. Unquote. For the health people, a new era begins: it is the era of specialism in preventive medicine.

BROCKINGTON, F. Letter from Great Britain. *Canad. Pub. Health J.* 38, 8:401 (Aug.), 1947.

Papers-of-the-Month—We have at long last an opportunity to cope on a broad, nation-wide scale with America's major public health problem—mental illness. So begins a discussion of the practical measures for the attack. If you are not sufficiently interested in what's to be done to read one of these papers, then you are too parochial minded for your own good.

FELIX, R. H. State Planning for Participation in the Mental Health Act. *Pub. Health Rep.* 62, 33:1183 (Aug. 15), 1947 (and) *The Battle Is Joined. Survey* Midmonthly 83, 9:235 (Sept.), 1947.

Slogans De-Watered —Something more is required than cheap, worn out slogans which are unconvincing and untrue, insists this British M. O. H. There really are advantages in breast feeding which are both convincing and true—he says. Incidentally, I wish more American health workers could and

would read the Health Education Journal. It's quite a periodical—and so very British.

GEFFEN, D. H. Science of Breast Feeding. Health, Ed. J. 5, 3:101 (July), 1947.

Another Epidemiologic Uncertainty—Textbooks set the incubation period for polio at 6–12 days, averaging 10. These figures are not well established, say the writers. Intervals between apparent exposure and onset vary from 3 to 35 days. Many factors need to be settled before we shall have exact knowledge, they conclude.

HORSTMANN, D. M. and PAUL, J. R. The Incubation Period in Human Poliomyelitis and Its Implications. J.A.M.A. 135, 1:11 (Sept. 6) 1947.

First, Choose Parents With Good Teeth—Children continuously drinking fluoride containing water are protected against caries but the degree of protection varies. Youngsters whose parents have the most dental disease are protected the least. It seems that familial susceptibility must be reckoned with in judging the beneficent effects of exposure to fluorine.

KLEIN, H. The Family and Dental Disease. Pub. Health Rep. 62, 35:1247 (Aug. 29), 1947.

Eight Years After—Evidence is presented here to suggest that people generally are continuing to improve in the matter of prompt action when they suspect cancer. Family physicians are not making comparable progress. In over 80 per cent of the patients studied, a diagnosis of cancer could have been made by the first physician if only he had made a careful history and physical examination. Has public health a bigger job to do here?

LEACH, J. E. and ROBBINS, G. F. Delay in the diagnosis of Cancer. J.A.M.A. 135, 1:5 (Sept. 6), 1947.

Men at Work—Did you know that for twenty years the U.S.P.H.S. has

maintained a venereal disease research laboratory on Staten Island? All sorts of interesting studies have been undertaken in the fields of diagnosis, prophylaxis, and therapy.

MAHONEY, J. F. Some Significant Aspects of Venereal Disease Research. Ven. Dis. Inform. 28, 7:129 (July), 1947.

Out of the Mouths, Et Cetera—School Children were asked to list the subjects taught in order of their preferences. Hygiene was promptly condemned to outer darkness, along with grammar and another deadly subject tabbed memory gems. One candid tile wrote, "I dislike hygiene because it is so boring." Brings back your own youth, doesn't it?

MONASH, L. Why Children Dislike School. Understanding the Child. 16, 3:67 (June), 1947.

Barber Shops Spread It Too—When community outbreaks of *Tinea capitis* occur—and they do occur often—half-way measures are not likely to fill the bill. The U.S.P.H.S. control method has nineteen steps, and it works.

SCHWARTZ, L. Public Health Aspects of the Treatment of *Tinea capitis*. New York State J. Med. 47, 16:1782 (Aug. 15), 1947.

In Return for His "Stamp"—In preparation for the (British) National Health Service, local authorities are busily arranging their schemes for home nursing care of the insured patient. These services may be given by local department nurses or through arrangements with voluntary nursing organizations. Many of us will be curious about the outcome of the different methods.

WARR, K. Public Health Nursing in England. Pub. Health 57, 1:1 (Sept.), 1947.

Educational Job To Do—In a typical community a public health survey revealed 3 unsuspected cases of cancer for every 4 known cases. If the proportion held generally the public health

be much more prevalent than is commonly assumed. Case finding methods are reviewed.

WILKERSON, H. L. C. and KRALL, L. P. Diabetes in a New England Town. J.A.M.A. 135, 4:209 (Sept. 27), 1947.

First, Be Sure—Today the water works operator uses alum, chlorine, copper, iodine, halozone, iron, metaphosphates, sulfuric acid, carbonic acid, and sulfur to make safe and acceptable community water supplies. It has been urged that, in addition to purification we medicate water supplies with iodine

and fluorine. Iodine was tried and abandoned. Fluorine is being added experimentally in a number of communities. Wolman, Geiger, and Morse say that we should wait until the controlled experimentation is completed before going further. Morse suggests that it is questionable economy to medicate 100 gallons of water for the sake of the single gallon the residents will drink.

WOLMAN, A., *et al.* Should Public Water Supplies Be Used for Mass Medication? J. Am. Water Works A. 39, 9:834 (Sept.), 1947.

ASSOCIATION NEWS

OFFICERS, 1947-1948

President, Martha M. Eliot, M.D., Washington, D. C.

President-Elect, Charles F. Wilinsky, M.D., Boston, Mass.

Vice-Presidents:

G. D. W. Cameron, M.D., D.P.H., Ottawa, Ont., Canada

J. P. Fontenelle, M.D., Rio de Janeiro, Brazil

Emilie Sargent R.N., Detroit, Mich.

Treasurer, Louis I. Dublin, Ph.D., New York, N. Y.

Executive Secretary, Reginald M. Atwater, M.D., New York, N. Y.

Chairman of Executive Board, Abel Wolman, Dr.Eng., Baltimore, Md.

New Members of Executive Board:

Estella Ford Warner, M.D., Washington, D. C.

George M. Uhl, M.D., Los Angeles, Calif.

THE A.P.H.A. ANNOUNCES AN INCREASE IN DUES

At the Atlantic City Annual Meeting the Governing Council approved amendments to the By-laws providing for an increase in dues for the various grades of membership in the Association. This step was reluctantly taken to meet the rising costs of printing the *American Journal of Public Health* and furnishing other services to members. In recommending the dues increases, the Governing Council took cognizance of the fact that the membership dues have remained at \$5 since the Association was established in 1872 and that the Fellowship dues have been kept at \$10 since this grade of affiliation was established in 1922.

As of October 10, and effective with the calendar year 1948, the annual dues for members will be \$7, for Fellows \$12, and for a subscription to the *American Journal of Public Health*, \$7. The new rate for Life Membership will be \$200.

As a convenience to any members or Fellows who may wish to apply for Life Membership before the new rate goes into effect, the Governing Council ruled

that such persons may have until December 31, 1947, to apply. Applications for Life Membership which are received up to that date and accompanied by an initial payment of \$25 will be accepted at the \$100 rate. Upon applications for Life Membership received in the Administrative Office after December 31, 1947, the new rate will apply.

With the additional revenue that is obtained from the increased dues the Executive Board plans to expand the *American Journal of Public Health* and reestablish the *Year Book*, absorbing the recent 45 per cent increase of printing costs. In addition, the Board will attempt to meet at least in part the urgent requests for funds from the Association committees dealing with such vital matters as the recruitment and placing of engineers, physicians, and laboratory workers. There are requests for field services of A.P.H.A. staff from coast to coast which would require the entire increase of Association income from the change of dues.

The Governing Council acted on

recommendation of the Executive Board and the Committee on Eligibility after conducting an opinion poll which showed that the reasons behind the change were widely understood by the

membership. Among professional societies the A.P.H.A. is unique in having deferred this change until 1948, in which year several similar groups are raising dues a second time.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- Shirley Benham, Jr., M.D., M.P.H., 215 W. 14th, Port Angeles, Wash., Health Officer, Olympia Health District
- Robert S. Easton, M.D., 609 City-County Bldg., Pittsburgh, Pa., Director, Tuberculosis Control Division, Dept. of Health
- Edward J. Fitzgerald, M.D., 65 Ridge St., Glens Falls, N. Y., Health Officer, City of Glens Falls
- John M. Huff, M.D., Municipal Bldg., Norfolk, Va., Director, Dept. of Health
- Raymond F. Kaiser, M.D., National Cancer Institute, Bethesda, Md., Asst. Chief, Cancer Control, Subdivision, U. S. Public Health Service
- R. H. Laning, M.D., Health Office, Amherst, Va., Health Officer
- Rodrigue Latourelle, M.D., D.P.H., 7—St. Laurent, Louiseville, Que., Canada, Health Officer, Health Unit
- Leonard Maidman, M.D., Wilton, Conn., Health Officer
- Perry F. Prather, M.D., Health Dept., Hagerstown, Md., Deputy State Health Officer, Washington County, State Dept. of Health
- Rollin A. Raymond, 3733 N. Arkansas, Wichita, Kan., Exec. Secy., Kansas Crippled Children Commission
- Paul Richmond, Jr., M.D., 476 Main St., Worcester, Mass., District Health Officer, State Dept. of Public Health
- Francois F. Rougon, M.D., New Roads, La., Director, Pointe Coupee Parish Health Unit
- Lawrence L. Spitzer, M.D., 209 S. Campbell St., El Paso, Tex., Public Health Physician, El Paso City-County Health Unit
- R. L. Tuli, M.B., D.P.H., D.T.M., New Colony, Nagpur, C. P. & Berar, India, Director of Public Health, Government Public Health Dept.
- Harold R. Vogel, M.D., 637 City-County Bldg., Pittsburg 19, Pa., Director, Pittsburgh Syphilis and Venereal Disease Control Program

Camillo E. Volini, M.D., 4022 Sheridan Rd., Chicago, Ill., Supt. of Clinics, Municipal Tuberculosis Sanatorium

Laboratory Section

- Louise Baker, M.A., 918 Grove St., Elmira, N. Y., Head Bacteriologist, Arnot-Ogdon Memorial Hospital
- Merle P. Baker, Ph.D., Dairy Industry Dept., Iowa State College, Ames, Iowa, Teacher of Dairy Bacteriology
- Mary Leigh Beach, 1800 N. Edison St., Arlington, Va., Director of Laboratory, Arlington County Health Dept.
- Eleanor M. Beckman, 1098 W. Michigan, Indianapolis, Ind., Public Health Trainee, State Board of Health
- Albert M. di Gioia, 350 Post St., San Francisco, Calif., Director, San Francisco Polyclinic
- Malcolm K. Dulaney, 410 E. 5th, Austin 2, Tex., Asst. Immunologist, Biologics Division, State Health Dept.
- William G. Godbey, P. O. Box 428, Weslaco, Tex., Director of Laboratory Division, Engineering Service and Sales Co.
- Venton R. Harrison, Wye Ave., Easton, Md., Assoc. Bacteriologist, Branch Laboratory, State Dept. of Health
- Carolyn J. Irwin, 610 Felder Ave., Montgomery, Ala., Assoc. Bacteriologist, State Dept. of Public Health
- Helen J. Kearney, 2824 Prince St., Berkeley 5, Calif., Student, Univ. of California
- Janice B. McLeod, 2116 Durant Ave., Berkeley 4, Calif., Student, Univ. of California
- James A. McDonald, Box 94, Woodlawn Hills, Calif., X-ray Technician, Laboratory
- John H. McGinness, Otisville, N. Y., Junior Bacteriologist, Municipal Sanatorium, Dept. of Hospitals, New York City
- Wanda C. McGuire, 2960 Broadway, Indianapolis, Ind., Bacteriologist, State Board of Health
- Jay D. Myers, 1765 W. 50th St., Los Angeles

37, Calif., Clinical Laboratory Technician, Los Angeles Sanatorium
 Iris Myers, 4705 E. 35th St., Indianapolis, Indiana, U. S. Public Health Trainee, State Board of Health
 Z. John Ordal, Ph.D., Guardian Bldg., St. Paul 1, Minn., Chief, Bacteriology Section, Research and Development Division, Economics Laboratory, Inc.
 Luis V. Pascual y Carol, M.D., Calle No. 9, N. 254, Havana, Cuba, Asst. Director, Laboratorio Biologico, Columbia, Mariane, Cuba
 Keith L. Sessions, 280 B. St., Salt Lake City, Utah, Junior Serologist and Bacteriologist, State Health Dept.
 Maurice Steinmetz Tarshis, M.S., U. S. Veterans Hospital, Clinical Laboratory Division, Walla Walla, Wash., Medical Bacteriologist, In Charge of Clinical Laboratory
 Kathryn Teeple, Campana de Bananera, Costa Rica, For Quepos, Medical Dept., San Jose, Costa Rica, Chief Medical Technologist, United Fruit Company Hospital
 Louise M. Ward, M.P.H., State Laboratory of Hygiene, Raleigh, N. C., Assoc. Bacteriologist
 Helen E. Woolley, 4038 Gladys Ave., Chicago 24, Ill., Senior Bacteriologist, Chicago Board of Health Laboratories

Vital Statistics Section

Harold A. Kahn, 3530 39th St., N. W., Washington 16, D. C., Biostatistician, U. S. Public Health Service, Venereal Disease Division
 Sarah L. Malisoff, 2124 Eye St., N. W., Washington, D. C., Analyst, Marriage and Divorce, U. S. Public Health Service
 Edward E. Schwartz, M.A., R. F. D. 1, Alexandria, Va., U. S. Children's Bureau, Director, Division of Statistical Research
 Daniel D. Swinney, M.A., 2706 Holly St., Alexandria, Va., Public Health Administrator, Division of Public Health Methods, U. S. Public Health Service
 John D. Thewlis, M.S., Division of Hospital Facilities, U. S. Public Health Service, Wash., D. C., Chief, Statistical Services Section

Engineering Section

Langdon B. Backus, Brownsville, Md., Research Secy., Philadelphia Tuberculosis and Health Assn.
 Paul L. Brooks, 34 South St., Middletown, N. Y., District Milk Sanitarian, State Dept. of Health
 Wade E. Eller, Boone, N. C., Sanitarian,

Alleghany-Ashe-Watauga District Health Dept.
 Reamy C. Fitch, P. O. Box 1226, Phoenix, Ariz., Senior Sanitary Engineer, Sanitary Engineering Division, State Board of Health
 Andrew J. Glenn, 23 Charlton St. East, Savannah, Ga., Sanitary Engineer, Savannah-Chatham County Health Dept.
 William A. Hansell, Jr., Health Dept., Griffin, Ga., Public Health Engineer, Spalding-Lamar-Pike Tri-Unit Health Dept.
 Kerwin L. Mick, M.S., 639 E. 57th St., Minneapolis, Minn., Chief Engineer and Supt., Minneapolis-St. Paul Sanitary District
 John V. Miner, Jr., Georgia School of Technology, Box 886, Atlanta, Ga., Laboratory Asst. and Student
 Stuart C. Mount, D.V.M., City Hall, Room 607, Milwaukee, Wis., Milwaukee Health Dept., Bureau of Food and Sanitation
 Oswald J. Muegge, M.S., 656 Crandall Ave., Madison 5, Wis., Sanitary Engineer, State Board of Health
 Felix C. Pickron, P. O. Box 129, Albany, Ga., Regional Engineer, State Dept. of Public Health
 Ray A. Scott, State Dept. of Public Health, 7 B. St. Pier Bldg., San Diego 1, Calif., Supervising Inspector, San Diego District
 Jack G. Sieg, 114 E. Edwards, Springfield, Ill., Senior Sanitary Engineer, State Dept. of Public Health
 Charles C. Spencer, 600 W. 168th St., Columbia Univ., New York 32, N. Y., Asst. Professor of Sanitary Science, School of Public Health
 E. J. Sylvester, 6516 People, New Orleans, La., Director, State Typhus Control, State Dept. of Health
 John Taylor, M.S., 1098 W. Michigan, Indianapolis 7, Ind., Director, Division of Dairy Products, State Board of Health
 James W. Wright, 54 Viale Parioli, Rome, Italy, Chief Sanitary Engineer, International Refugee Organization

Industrial Hygiene Section

Ralph T. Behling, M.D., 1146 Appraisers Bldg., San Francisco 11, Calif., Cancer Control Consultant, U. S. Public Health Service
 Bertrand Bellemare, M.D., M.P.H., 575 15th St., Limoilou, Que., Canada, Chief, Service de la Medecine du Travail, Ministry of Labor

NEWS FROM THE FIELD

THE PRINCETON CONFERENCE ON LOCAL HEALTH UNITS

Representatives of 65 national citizens' organizations met at Princeton University, September 8-10, in a Conference on Local Health Units to discuss practical possibilities and methods of providing adequate public health services for every citizen in the United States. These agencies and their state and local branches represented not less than 50,000 points of public influence and education.

The conference, called by the A.P.H.A. Subcommittee on Local Health Units, provided the first opportunity for representatives of the general public to consider the problem of adequate coverage of the nation by local public health services. An earlier conference in Ann Arbor, Mich., in September, 1946, had been attended by the official administrative officers of the 48 state departments of health. Both meetings were made possible by grants from the W. K. Kellogg Foundation.

As a result of the Princeton conference, the citizen groups called upon the A.P.H.A. to provide immediate guidance and leadership in helping to define health problems and in providing an overall guide for operations of participating organized citizen groups in establishing and strengthening local health services.

The formation of state-wide citizen health groups was recommended to coordinate public participation in programs for community health services in each state. The group also endorsed the necessity for local health councils but stressed the need for professional participation in the planning and activities of these councils.

The opening address of the conference was given by Dr. Haven Emerson, Chairman of the A.P.H.A. Subcom-

mittee on Local Health Units, who declared, "Local government that fails to serve its people by providing basic health services is a failure in democracy."

Dr. Emerson added, "There can be no substance or reality in health organizations at the state, national, and international levels unless the base, the foundation structure, the essential functioning element in all public health service is developed, accepted, and supported at the local or community level."

"Without the framework and organization of local health departments directed and staffed by professionally qualified full-time employees, all private effort and private funds (expended for health purposes) will be largely wasted or will be applied usefully only in those areas where competent local health service is being already provided."

Repeating the findings of the A.P.H.A. survey published by the Commonwealth Fund in 1945 in *Local Health Units for the Nation*, Dr. Emerson told the delegates that 41,000,000 people in the United States are "living in communities which lack full-time, modern, local health departments for providing even the six basic health services considered indispensable . . . It appears that there are approximately 155,000 local government jurisdictions which may, if they wish, set up local health departments in the United States. There are, in fact, some 18,500 such local health departments. There are 3,070 counties in the 48 states. In the opinion of the Committee on Local Health Units of the A.P.H.A., not more than 1,200 local health departments are needed to cover the nation."

The basic structure and functions of a local health department were presented

to the delegates by Dr. Wilson G. Smillie, Professor of Preventive Medicine and Public Health at Cornell University Medical College. He pointed out that "a local health department is one which is organized to meet adequately the health needs of a governmental unit smaller than the state." Dr. Smillie's presentation was further elaborated in addresses by Dr. T. Paul Haney, Bureau of Maternal and Child Health, Florida State Board of Health, Dr. Mack I. Shanholtz, Division of Preventive Medicine, Oklahoma State Health Department, and by Mrs. O. L. Webb of the Nebraska Statewide Health Committee.

What a local health department is, according to these speakers who represented educators, lay citizens, and local public health administrators, may be summarized in the six items below. Grass roots responsibility arising out of local popular understanding was stressed by each speaker.

A local health department should do at least the following for its community:

1. Keep the facts of births, deaths, sickness, and make them available for use in planning community health programs, school services, industrial health services, and hospital and medical care facilities.
2. Carry out all necessary activities to control communicable and preventable diseases such as tuberculosis, venereal diseases, malaria, hookworm disease, and the communicable diseases of childhood.
3. Supervise the health of the mother and the child from birth through school years, finding the remediable defects of eyes, hearing, teeth, nutrition, and posture, and providing for their correction either directly or through existing community facilities.
4. Supervise the physical surroundings of the community and coördinate the necessary activities for making it favorable to health and well-being. This means providing for clean water, milk, and food, for healthful housing, working conditions, proper sewage disposal, and sanitary recreation facilities, and for safety in home, school, and shop.
5. Provide public health laboratory service both to carry out its own job and to assist

practising doctors of the community in diagnosis and treatment.

6. Carry on public health education, making known to the people generally the facts of modern biology and science, and giving instruction in the use of such facts to keep in good physical health.

Dr. Florence R. Sabin, Health Chairman of the Colorado Post-War Planning Committee, spoke on "How Citizens Make Their Wishes Known." Dr. Sabin outlined a recent campaign in which she was active in Colorado which resulted in replacing health laws passed in 1876 with modern legislation. Two conditions are necessary, she said, before reorganization of health services for the people's benefit could be achieved: (1) the people must know the facts about the health and sanitation conditions in their communities, and (2) demonstrations must be given of the exact contributions which preventive medicine can contribute to their lives.

Dr. Sabin added that in Colorado the success of the campaign was due to the activities of organized groups in local communities in informing the public and bringing pressure for legislative action. The people of Colorado were so well informed and so aroused about the public health situation in the state, that their legislative representatives had no choice but to pass the proposed laws and to authorize appropriations necessary to carry out their purposes.

The part that voluntary organizations can play in developing wider public knowledge and demand for modern local health services was presented by two representatives of such organizations, George J. Nelbach of the New York State Committee on Tuberculosis and Public Health, and James G. Stone of the National Tuberculosis Association. Mr. Stone quoted the 1947 platform of the National Tuberculosis Association: "Tuberculosis services to be most effective should be integrated with general community health facilities. To that

end, tuberculosis associations should work to secure the establishment of adequately staffed local health services." He urged the need for this plank in the platforms of other national health agencies.

The great lack of adequate health services in rural areas was emphasized by Dr. Fred Mayes, Director of the Division of Local Health Administration, Kansas State Health Department. The solution proposed was consolidation of several thinly populated counties into public health units, which, although expanded in area and assisted by state leadership, would still be locally operated community agencies. The minimum population that can well support a local health department is 50,000; a larger population when feasible.

Other speakers were Dr. Henry F. Vaughan, Dean, University of Michigan School of Public Health, who discussed "Financing and Staffing of a Local Health Department." He reminded his audience that "health is a purchasable commodity, as essential to man's well-being as food, fuel, shelter, and clothing."

Dr. Joseph McLean, Professor of Government, Princeton University, in a paper entitled "Local Government in Relation to Local Health Service," outlined the complexities of local, state, and federal relationships, both administrative and financial, that must be considered in organizing local activities, health service no less than others. Dr. McLean warned that the process of consolidating municipalities into county or district units in New Jersey and the New England states would be slow but must nevertheless be undertaken. He cited a 1937 study of local government in New Jersey which arrived at the conclusion that most of the official services of government—health, welfare, sewage disposal, fire and police protection, and many others—are best done in population units of at least 50,000.

Dr. G. F. Moench, Hillsdale, Mich., Health Chairman of the National Congress of Parents and Teachers, discussed the ways in which the national agency can get this message to its local branches. Among his suggestions were a clear-cut national program in which local branches can participate, and co-operation between national and local agencies in carrying out a unified community program.

Following the presentation of papers, morning and afternoon, the delegates separated into smaller groups for discussion. An enthusiastic purposeful approach to the problems posed was demonstrated by the four lively discussion periods. Discussion leaders were selected from the invited representatives of the citizen organizations.

The great stress on the necessity for an informed citizenry led to the suggestion that the minimum personnel standards promulgated by the A.P.H.A. be expanded to include a health educator on the staff of each local health unit of adequate size for economical and efficient operation.

The development of model plans by national associations for the promotion of active well informed committees through their state and local affiliations was recommended as a means of developing a strong public opinion in support of local health programs. In developing such model plans, the national citizen agencies proposed that the American Public Health Association develop facilities for furnishing guidance and help to the national agencies.

A word should be said about what one delegate called "the exalted feeling that pervaded the last quarter hour." Bailey B. Burritt, Director of the National Health Council, and Dr. Sabin each summed up some of the aspects of the conference. Said Mr. Burritt, "We have developed not only a new factual appreciation of the necessity for local health units but an awakening of our

emotional appreciation of this fact. However, unless this factual and emotional appreciation leads to action, this conference will not have achieved its main purpose."

Dr. Sabin summed up some of the slogans that had come out of the meeting, such as "We cannot get public health overnight but we should work as if we could," "Adult education is submerged leadership," "Preventive medicine is economically sound," "Public health is public wealth," and finally a quotation from Ralph Waldo Emerson, "What will you have? quoth God. Pay for it and take it."

Following are the resolutions passed by the conference:

Resolution Presented at the National Conference on Local Health Units, by J. S. Jones, Secretary, The Minnesota Farm Bureau Federation:

Public health is public wealth. The greatest actual and potential asset of the United States, of each state and each local unit of government is a vigorous, healthy citizenry. Recognizing the great advances that have been made in preventing unnecessary illness and the maintenance of health, it is still true that there is a wide gap between knowledge and practice in the protection of the health of the people.

This is a problem that concerns every person. It is at once an individual and collective responsibility. The realization of a high degree of health of the people of these United States cannot be achieved while forty-one million persons are residing in areas without the protection of a local health unit manned by a full-time, well trained public health official and sufficient staff to render skilled health services.

This situation has been reviewed thoughtfully by representatives from sixty-five na-

tional voluntary organizations in a conference at Princeton, N. J., under the auspices of the American Public Health Association. As a result of their deliberations they are of the unanimous opinion that this is an immediate challenge. The war emphasized the challenge, and now the necessity of organization for a stable future gives it renewed emphasis. The opportunity is great and its achievement practical.

As representatives of these 65 national citizens' organizations we are now prepared to urge upon each such organization the immediacy of this challenge and the great opportunity it offers, and to urge further that vigorous steps be taken by each agency through national, state, and local branches to include in their programs of work completion of health unit coverage of all areas so that at least minimum protection may be given to the maintenance of health of every person.

Motion presented by Miss Ruth Bottomly, Executive Secretary, National Congress of Parents and Teachers

Moved that the members of the National Conference on Local Health Units request the American Public Health Association to make available in some published form the complete proceedings of the Conference, sending one copy to each agency represented and making others available for purchase.

Motion Presented by Mr. George Nelbach, New York State Tuberculosis and Health Association:

On behalf of the agencies represented at the National Conference on Local Health Units, I move a resolution of thanks to the American Public Health Association for its wisdom and sound judgment for the privilege of participating in this Conference, and also to include in our gratitude Princeton University for making the meeting facilities available and also to the W. K. Kellogg Foundation for the grant of funds to the American Public Health Association which made the Conference possible.

SEWAGE RESEARCH

The Federation of Sewage Works Associations, through its Executive Secretary, W. H. Wisely, announces a grant of \$33,830 from the Research Grant Division of the National Institute of Health. "The object of the research

will be to evaluate existing methods of analysis of sewage and industrial wastes with respect to dependability and accuracy, and to devise where possible, improvements on entirely new methods . . . The research will be conducted in six selected laboratories, each being

under the direction of a member of the Federation's Standard Methods Committee."

The following laboratories have already been selected for certain phases of the work: Illinois State Water Survey; Mellen Institute; New York State Division of Laboratories and Research; Rutgers University, Department of Sanitation; Wisconsin State Laboratory of Hygiene.

UNITED STATES MAKES ISOTOPES AVAILABLE TO THE WORLD

At the recent fourth International Cancer Research Congress in St. Louis, announcement was made by President Truman lifting the ban against the exportation of radioactive isotopes to scientists of foreign countries. By this action of the United States Atomic Energy Commission, these important research tools became available for medical and biological investigations outside the United States.

The gathering of scientists from 35 countries and its President, Dr. E. V. Cowdry, Professor of Anatomy, Washington University, hailed this message as a "momentous event" of great significance to scientists and to mankind all over the world.

The message also gave impetus to the setting up of a world-wide organization against cancer, a by-product of which it is hoped will be an example in international coöperation in the diplomatic and political fields as well.

Australia was the first nation to avail itself of the privilege of purchasing isotopes. On September 5, 20 millicuries of phosphorus 32 for treatment of an urgent case of a blood disorder, polycythemia vera, were shipped by air to the Commonwealth X-ray and Radium Laboratory of Melbourne.

U. S. SENATE APPOINTS CITIZENS' ADVISORY COUNCIL OF SOCIAL SECURITY A Senate resolution adopted before

the adjournment in July of the Congress and sponsored by Senators Millikin of Colorado and George of Georgia has become effective, providing for a "full and complete investigation" of social security and the various proposals for enlarging the present program. An appropriation of \$25,000 has been made to implement the project.

Edward R. Stettinius, Jr., former Secretary of State and now Rector of the University of Virginia, has been appointed Chairman of the 17 man committee. Associate Chairman is Professor Sumner H. Slichter of Harvard University, who is also Chairman of the Research Advisory Board of the Committee on Economic Development.

Dr. Florence R. Sabin of Denver, Chairman of the Denver Board of Health and well known proponent of full-time public health service in Colorado, was made a member of the committee. Other members include Frank Bane, Chicago, Executive Director of the Council of State Governments; J. Douglas Brown of Princeton University; Nelson H. Cruikshank, Director of social insurance activities of the American Federation of Labor; Mary H. Donlon of New York, Chairman of the State Workmen's Compensation Board; William I. Myers of Ithaca, N. Y., Dean of the New York State College of Agriculture, and Emil Rieve, Vice-President of the Congress of Industrial Organizations.

DEGREE CHANGES AT NORTH CAROLINA

The School of Public Health of the University of North Carolina, Chapel Hill, has announced that with the beginning of the school year, September, 1947, the Degree of Master of Science in Public Health will no longer be awarded. The only degrees to be awarded will be the Master of Public Health, the Doctor of Public Health, the Master of Science in Sanitary Engineering, and the Certificate and Bachelor of Science in Public Health

Nursing. The largest group among the students to be affected by the change in degrees will be the health educators, who hereafter will receive the M.P.H. instead of the M.S.P.H.

WHO PUBLIC HEALTH FELLOWSHIPS

Of the approximately 200 fellowships that will be granted to public health specialists for study outside their own countries, 66 have already been provided by the Interim Commission of the World Health Organization. This is the first selection of doctors, nurses, and other public health workers under an exchange program whereby scientists and medical specialists will share in advances of medical knowledge on a world-wide basis.

The first group selected includes 18 fellows each from China and Yugoslavia, 15 from Czechoslovakia, 5 from Finland, 4 from Austria, 3 from Poland, 2 from Northern Korea, and 1 from Greece.

PHYSICIANS ADVISE ATOMIC ENERGY COMMISSION

The appointment has been announced of the Advisory Committee for Biology and Medicine of the United States Atomic Energy Commission which held its first meeting in Washington on September 11 principally to determine how the Commission should spend five million dollars appropriated by Congress for cancer research, and with reference to the head of the Division of Biology and Medicine of the A.E.C. The committee will study the basic policies relating to the medical, biological and health aspects of the Atomic Energy Program. This will include research on possible health hazards in the development of atomic energy and the extension of medical and biological research and development, and on the improvement of coöperative relationships with the Armed Forces and with the U. S. Public Health Service.

Among the members of the com-

mittee are Alan Gregg, M.D., Director for Medical Sciences, Rockefeller Foundation, New York, Chairman; Ernest W. Goodpasture, M.D., Dean of the School of Medicine and Professor of Pathology, Vanderbilt University, Nashville, Tenn.; A. Baird Hastings, Professor of Biochemistry, Harvard Medical School, Boston, Mass.; and Joseph T. Wearn, M.D., Dean of the School of Medicine and Professor of Medicine, Western Reserve University, Cleveland, Ohio.

MASSACHUSETTS PUBLIC HEALTH CONFERENCE

A Conference under the sponsorship of the University of Massachusetts, the Massachusetts Public Health Association, and the Massachusetts Department of Public Health, was held in Amherst, September 11-12. Local arrangements were in charge of Professor Ralph L. France of the Department of Bacteriology, University of Massachusetts.

The 2 day session included addresses by Dr. Charles F. Wilinsky, President of the Massachusetts Public Health Association; Dr. Hugo Muench, Harvard School of Public Health; Dr. Vlado A. Getting, Commissioner of Public Health; and by a group of speakers who reviewed developing plans for complete coverage of the state with full-time local health units. Among these were Dr. Alfred L. Frechette, Health Officer of Brookline; Charles A. Freck, Queensboro Tuberculosis and Health Association; Dr. Haven Emerson, Chairman of the Subcommittee on Local Health Units, American Public Health Association; Dr. Hugh R. Leavell, Harvard School of Public Health; and Dr. Reginald M. Atwater, Executive Secretary, American Public Health Association. The dinner session was addressed by Dr. Herman E. Hilleboe, newly appointed Commissioner of Health of New York State.

Other speakers included Dr. John F.

Conlon, Director of Medical Education and Information, Massachusetts Medical Society; Miss Mildred Lant, Assistant Director of Public Health Nursing, New York City Department of Health; Dr. Walter Mallmann, Professor of Bacteriology, Michigan State College; Professor Gordon M. Fair, Harvard School of Engineering; Dr. Geoffrey Edsall, Division of Biological Laboratories; Dr. Alton S. Pope, Deputy Commissioner of Public Health; also Lewis Dodson and Walter Snyder of the National Sanitation Foundation, Ann Arbor, Mich.

Total attendance was about 400. It is anticipated that this will become an annual event, and tentative dates have been set for June 16 and 17 in Amherst in 1948.

HANSEN MEDAL TO PROFESSOR WAKSMAN

During the Fourth International Microbiological Congress held in Copenhagen, Denmark, July 20-26, the Emil Hansen Medal and an award of 5,000 kroner was presented to Professor S. A. Waksman, Agricultural Experiment Station, New Brunswick, N. J., for his studies in the field of the antibiotics. Professor Waksman announced that the money presented would be used for the support of work now being carried out by a Danish graduate student at New Brunswick.

DR. HELMHOLZ HONORED

At the recent International Congress of Pediatrics in New York, Henry F. Helmholtz, M.D., Professor of Pediatrics, Mayo Foundation, University of Minnesota, was awarded certificates of honorary membership in the Latin American Division of the American Academy of Pediatrics and in the Sociedade Brasileira de Pediatrics. He also was decorated in the National Order of Merit of Carlos J. Finlay in the grade of Commander from the Cuban Government in recognition of his services in

furthering pediatric practice in Latin American countries.

OPPORTUNITIES FOR NAVAL RESERVE MEDICAL OFFICERS

The Naval Air Reserve Training Command, with headquarters at Naval Air Station, Glenview, Ill., has 17 nationally located Naval Air Stations and 4 Naval Air Reserve Training Units at which Naval Reserve Medical Officers may serve on active duty with full pay and allowances and with the privilege of returning to civilian life at any time upon request. Additional details may be obtained from Chief of Naval Air Reserve Training, Naval Air Station, Glenview, Ill.

ONE YEAR OF RAT CONTROL

The monthly news sheet, "Rat Controller," July, 1943, of the St. Louis Health Division, makes special recognition of the completion of the first year of activity of the recently established Rat Control Section. The activities of the Section have been divided among four general services. Emphasis has been placed on education of the public through the Education Service. Actual long-range field control has been divided between the Rat-Stoppage Service and the Rat Eradication Service. The fourth Service, that of Inspection-Enforcement, handles complaints requiring day-to-day activities. A full-time biologist has been added to the staff to conduct biological studies and to keep informed on the presence of murine typhus. All of this work, under the direction of John L. Sadowski, Chief of the Rat Control Section, is an outcome of the Rat Control Ordinance adopted on June 26, 1946. J. F. Bredeck, M.D., Dr.P.H., is Health Commissioner.

TUBERCULOSIS RESEARCH CENTER TO SUPPLY BCG VACCINE

The recent Illinois Legislature authorized the construction and maintenance

of a tuberculosis research hospital in conjunction with the University of Illinois College of Medicine, Chicago. It includes an appropriation of \$361,250. The Institute for Tuberculosis Prevention, which will be built on the medical campus and be run in close coöperation with the City of Chicago Municipal Tuberculosis Sanitarium, will supply BCG vaccine for the U. S. Public Health Service, now carrying on a project in Columbus, Ga., for a long-range study of the vaccine. The vaccine, which can be manufactured at a cost of about half a cent per dose, will be distributed to regular health agencies, city, state, and federal, but not on commercial lines.

The Research Foundation Board headed by Park Livingston, president of the trustees of the University of Illinois College of Medicine, Chicago, has been set up to raise additional funds for operation of the Institute.

NEW NUTRITION DEPARTMENT AT NORTHWESTERN UNIVERSITY

Northwestern University and the Spies Committee for Clinical Research will establish in Chicago a center for medical research in the field of nutrition and metabolism. The agreement provides that Tom D. Spies, M.D., Associate Professor of Medicine at the University of Cincinnati, will become Professor of Nutrition and Metabolism and Chairman of a new department in this field in the Medical School of Northwestern University. Following his resignation from the University of Cincinnati, he assumed his new duties September 1, at which time the Spies Committee severed its relationship with the University of Cincinnati.

The agreement further provides that the committee will grant to the university at least \$150,000 annually for five years to be used for the expenses of this department and for research carried on under Dr. Spies. The Spies Committee for Clinical Research was organized in

1943. Dr. Spies in 1937 organized, and has since directed, the University of Cincinnati studies in nutrition at the Hillman Hospital Nutrition Clinic, Birmingham, Ala., and this work will continue under his direction.

SAN FRANCISCO COMMUNICABLE DISEASE PRECAUTIONS

Dr. J. C. Geiger, Director of Public Health, City and County of San Francisco, announces that because of the recent transportation of cases of communicable disease into San Francisco by airplane, the following necessary precautions have been suggested and made mandatory as far as San Francisco is concerned:

1. Permission should be obtained for trans-
ferral of case
 - a. local health authority
 - b. state health authority of place of destination
 - c. local health authority of place of destination
2. If disease has been recognized or classified as suspected disease, precautions are mandatory,
 - A. If spread by contact, attendants should be required to wear surgical gown over clothes, face masks, even goggles. Such garments and materials should be gathered in suitable bags (paper or cloth) and sterilized by autoclave heat or burned in suitable ovens.
 - B. The plane itself must be aired thoroughly, interior washed by soap and water, and if disease is spread by insect vectors (mosquitoes, fleas, lice, etc.) additionally sprayed with suitable aerosol vapors.
3. Since a case of communicable disease should not travel in a public plane conveyance with other passengers, there is no need for protection of fellow passengers other than attendants.
4. Utensils used by patients should be kept separate and boiled for ten (10) minutes
5. Blankets and other coverings of patient must be sterilized by sunning, by steam and laundering.

6. The airplane crew must avoid contact with patient and attendants. The plane must be fully equipped with proper bed, heating, first aid outfits, drugs, and oxygen.
7. Patients should be moved to and from plane by special ambulances.
8. Airfields attendants must offer all and immediate clearance necessary to proper handling of case

Explanation: The airplane and its value in swiftly and safely moving wounded was amply demonstrated in war II. Similar use of the airplane in civilian life has unlimited possibilities in saving time and reducing mortality from disease and accident. It appears to be a prime necessity in all areas where airport facilities are being so well developed as in San Francisco.

J. C. GEIGER, M.D.

Director of Public Health
City and County of
San Francisco, Calif.

DR. FLORENCE R. SABIN ELECTED
HONORARY FELLOW OF A.P.H.A.

At the meeting of the Governing Council in Atlantic City, N. J., on October 8, Florence R. Sabin, M.D., of Denver, Colo., was unanimously elected an Honorary Fellow of the Association in recognition of the extraordinary achievements which she has spearheaded in the public health program of Colorado. Dr. Sabin holds among other honors the Jane Addams Medal for Distinguished Service, the Trudeau Medal of the National Tuberculosis Association, and she is currently the President of the Western Branch of the American Public Health Association and President of the Denver Board of Health. Dr. Sabin, who is a native of Colorado, recently retired as a member of the Rockefeller Institute for Medical Research after an extended career in science. Dr. Sabin was the featured speaker at the Princeton Conference on Local Health Units sponsored by the American Public Health Association, September 8-10.

PERSONALS

Central States

HAROLD S. ADAMS,* has been appointed Director of the Division of Hotel and Resort Inspection, Section of Environmental Sanitation, Minnesota Department of Health, succeeding THEODORE T. WOLD who resigned to enter private business. Mr. Adams will continue to serve as lecturer in the School of Public Health of the University of Minnesota. He was formerly Chief of the Bureau of Environmental Hygiene, Minneapolis Department of Health. He recently wrote *Milk and Food Sanitation Practice* which was published by the Commonwealth Fund.

JOHN BUXELL,* Engineering Director of the Health Division of the City of St. Louis, Mo., is on leave for a year's study toward a Master's degree in Public Health, at the University of Minnesota, Minneapolis, Minn.

ELIZABETH COLLINS has been appointed Consultant in Nutrition to the Public Health Nursing staff of the Cleveland Division of Health, Cleveland, Ohio.

MARY CATHERINE DONOVAN took charge of the Public Relations Department at the Cleveland Museum of Health, September 1. She has been the Director of Public Relations at Notre Dame College, South Euclid, Ohio, for the past three and one-half years.

CHANGES IN HEALTH PERSONNEL IN KANSAS:

FRED MAYES, M.D.,† Assistant State Health Officer and Director, Division of Local Health Administration, Kansas State Board of Health, has been granted educational leave to complete his work on a Master's degree in Public Health at Harvard University.

THERESA JENNIGES* has been appointed Director of Public Health Nursing Services for the State Board of Health. Her public health experience includes work at local, state, and national levels with the Hennepin County Rural Nursing Services, Minnesota; Instructor, Public Health Nursing, Loyola University; Supervisor, Maywood Teaching Center, Chicago; Associate Public Health Nursing Consultant, U. S. Public Health Service, assigned to South Dakota as Supervising Nurse and Senior Assistant Nurse Officer (R) assigned to Oregon and Georgia State Health Departments.

VERNON M. WINKLE, M.D.,† formerly Assistant Health Officer of the Topeka City-Shawnee County Health Department, Kan., has been appointed Acting Director of the Division of Local Health Administration in the absence of Dr. MAYES.

A. B. ROSENFELD, M.D., M.P.H.,† has been appointed Director of State Health District No. 6, comprising 7 of the counties of Minnesota, with headquarters in Minneapolis. He was formerly Director of School Health of the Hibbing, Minn., public schools.

LEONA RUBBELKE† and RUTH ANDERSON have been appointed respectively as Nursing Consultant in Maternal and Child Hygiene and as Nursing Consultant for the Hospital Construction Program of the North Dakota State Department of Health.

Eastern States

PAUL BENJAMIN recently resigned as Secretary of the Pennsylvania Charities Association to become Executive Secretary of the Related Activities Council of Schenectady, N. Y. He

has been succeeded in Pennsylvania by HUGH JACKSON, who has had experience with a number of social agencies, the New York State Charities Aid Association, UNRRA, and, most recently, the National Social Welfare Assembly.

ELLIS H. CHAMPLIN,† who has been serving as Acting Director of the Division of Health and Physical Education of the New York State Education Department in Albany since 1945, has been appointed Director of the Division effective September 11. Mr. Champlin was formerly Chief of the Bureau of Physical Education in the Division he now directs.

LOUIS L. FELDMAN,† who before his recent military service was on the staff of the Committee on Administrative Practice, American Public Health Association, has been appointed underwriter and assistant to the general manager of the Health Insurance Plan of Greater New York.

S. S. LIFSON* has been appointed Assistant Director, Community Organization, of the National Health Council, New York, N. Y. Mr. Lifson was formerly Health Education Consultant with the U. S. Public Health Service, District 1, New York, N. Y.

CLARICE LEAVELL PENNOCK, on September 1 began her duties as Secretary of the National Conference on Family Life. She was formerly Executive Secretary of the Association of Junior Leagues of America, New York, N. Y.

HENRY B. MAKOVER, M.D.,† formerly Senior Surgeon, U. S. Public Health Service, and recently Associate Director of Montefiore Hospital for Chronic Diseases, New York, where he surveyed the possibilities of, and recommended a plan for, a hospital group-practice unit, has assumed the post of health and medical consultant to the Federation of Jewish Charities of Philadelphia, Pa.

JEROME S. PETERSON, M.D.,* on a year's

* Fellow, A.P.H.A.
† Member, A.P.H.A.

leave of absence as District Health Officer of the New York City Department of Health, returned to China on September 1 to serve as epidemiologist for the World Health Organization. His work will be mainly concerned with the study and control of cholera, bubonic and pneumonic plague, and kala-azar. For 10 months last year he served with the UNRRA as Chief Medical Officer in China.

BERTRAND E. ROBERTS, M.D.,† after 25 years' service in the New York State Department of Health retired recently. With the department since 1922, he was first epidemiologist and for the past 17 years District State Health Officer in the Poughkeepsie area.

NELSON W. STROHM, M.D.,† has been appointed Director of Tuberculosis Control in the Buffalo, N. Y., Department of Health. He has been associated with the chest clinic of the Division of Communicable Diseases of the Buffalo Health Department since 1919, and since February 1 of this year has been chief of the diagnostic clinic of the health department.

JESSIE TURNBULL, Administrator of Elizabeth Steel Magee Hospital, Pittsburgh, Pa., was elected the first woman President-Elect of the American College of Hospital Administrators at its 13th annual meeting, September 22, at St. Louis, Mo.

Southern States

RICHARD B. BLACKWELL, M.D., who has assumed the duties of Health Officer of Rockbridge County, Va., succeeds ROBERT P. COOKE, M.D., who retired after serving 20 years as Health Officer. Dr. Blackwell recently retired from the navy after 30 years of service.

CLARENCE L. GUYTON, M.D.,† has resigned as Director of the South Carolina State Board of Health Division of Venereal Disease and Cancer Control and accepted the appointment of City Health Commissioner at Greenville, S. C. Dr. Guyton organized and developed the state's cancer control program.

SAMUEL J. HAWKINS has been loaned by the U. S. Public Health Service, District 2, Richmond, Va., to the Bureau of Venereal Disease Control, West Virginia State Department of Health, as Field Epidemiologist.

JAMES G. MILLER, M.D., Chief of the Clinical Psychology Section of the neuro-psychiatric division of the Veterans Administration, Washington, D. C., has been appointed Chairman of the Department of Psychology at the University of Chicago, Chicago, Ill. Effective January 1, 1948, his appointment carries the rank of professor of psychiatry and psychology.

LEWIS J. MOORMAN, M.D., one of the founders and for the last 29 years president of the Oklahoma County Health Association, has been made "honorary president for life" of that organization. He assisted in the organization of the Oklahoma City Tuberculosis Society and was the first president in 1918.

W. PHILLIPS PALMER† assumed his duties as Consultant in Administration and Public Relations with the West Virginia State Department of Health, September 1.

EVELYN T. STOTZ, former Lieutenant Commander in the U. S. Navy Nurse Corps, has been appointed Nursing Director of the National Blood Program of the American National Red Cross, Washington, D. C.

GENEVA K. WATSON,† for 17 years a teacher in the Charlottesville, Va., schools, has been appointed by the Virginia Tuberculosis Association to supervise health education services in

The Stems and Roots of Public Health Practice*

HARRY S. MUSTARD, M.D., F.A.P.H.A.

Director, Columbia University School of Public Health, New York, N. Y.

THIS is the seventy-fifth anniversary of the founding of the American Public Health Association. The records indicate that on April 18, 1872, a group of physicians interested in public health matters held a morning conference in New York City. Evidently, they engendered an enthusiasm among themselves, for they held another session that afternoon and laid the groundwork for the formal establishment of a public health association, national in scope. The Association as such came into existence with the adoption of a constitution at a meeting held in Long Branch, N. J., September 12 of the same year.

It would be pleasant to go into these early events in detail, to pay tribute to Dr. Stephen Smith, the first president of the Association, and to cite the names and list the contributions of the Association's illustrious forebears. But of more practical importance than such an ancestral excursion is the institution of a search for those influences that have

made this Association and public health so different in 1947 from what it was in 1872. One might dispose of these changes by saying that the American Public Health Association and the practice of public health have grown with the times. But that is not a sufficient answer. The differences between then and now are too pronounced in both character and extent to be accounted for as mere shifting in a surface pattern. Their quality and quantity suggest, rather, that new and powerful influences were introduced at some one time, or intermittently, or continuingly, in the past seventy-five years.

As a starting point in this search for causes and influences, it seems worth while to study the social conditions that prevailed in 1872. For whatever it may mean, General Grant was in the White House. The population of the United States was about 39 million. The population of New York City was under a million and a half, and Los Angeles numbered less than 6,000. There were but 38 states and only 14 of them had a population of over a million. The population concentration was 13 persons per square mile. Indian skirmishes

* Presidential Address presented before the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 7, 1947.

were not a thing of the past and Custer was yet to be massacred. Vast cattle and farming areas were being opened up, manufacture, industry, and transportation were, comparatively speaking, in their infancy, as were the giant corporations and labor unions. The Federal Constitution was less than a hundred years old, but an interpretation by force of arms, only seven years before, suggested that a more powerful national government would exert jurisdiction in civil matters previously considered to be in the sphere of the states. While the nation was still an agricultural one, with 80 per cent of its population rural, the cities were growing. Vast immigrant hordes streamed into them and lived in abject poverty. Social consciousness was ill-defined and society did not expect government to expend its funds for social welfare. If there was a national concept or ideology, it was that each man must rise and shine, and conversely, there was the granite-hard philosophy that if one made no effort to rise he would most certainly not bask in the warmth of sunshine produced by others.

The half century preceding the year 1872 had been a time of epidemics. Cholera had entered the United States in 1832 and had been devastating in its effects. Another outbreak began in 1848 and went across the continent to California with the Forty-niners. A third cholera epidemic flared in 1866, and a fourth in 1873, the last particularly affecting the Mississippi Valley. Typhus fever had appeared intermittently in our Atlantic ports as immigrants poured in. Yellow fever epidemics came with rather distressing regularity in the South Atlantic and Gulf ports and occasionally much farther north. There were, too, recurring epidemics of non-exotic diseases—smallpox, typhoid fever, diphtheria, meningitis, malaria, dysentery, and others. Over and above those diseases that manifested themselves in

epidemic form, there was a high incidence of most of the ordinary human illnesses. But because the epidemics were more dramatic and terrifying, non-epidemic disease did not cause much public concern. Death rates were quite high as evidenced by the fact that in many of the cities in the middle of the century, deaths of children under one year of age made up 25 to 30 per cent of the total mortality, as against the 7 per cent of today. Life expectancy was about 40 years, whereas now it is 64.

The knowledge and mechanisms available for the practice of public health in 1872 were comparatively limited. Pasteur was still preoccupied with his studies on fermentation and pasteurization, and bacteriology was in an embryonic stage. There had been, of course, speculation and individual convictions as to the role of microorganisms in the causation of disease, but the first bacteria (anthrax) had not yet been grown in pure culture. Pettenkofer's XYZ doctrine on cholera had just been crystallized. Snow's essay on cholera had been published in 1849, and Budd's on typhoid fever was due to appear in 1874. Shattuck's *Sanitary Survey of Massachusetts* had been written in 1850, but was destined to gather some nineteen years of attic dust before his recommendations were acted upon. When the Association was formed, the United States Marine Hospital Service had been in existence for some three-quarters of a century but had been put on a national basis only two years before. The first supervising surgeon of that Service had just been appointed, and the Service's first *Annual Report* was published the year the Association was founded. Only five states had established state boards of health, Louisiana, Massachusetts, California, Minnesota, Virginia. The American Medical Association was 25 years old.

In the social environment that existed, in view of the problems that presented themselves, and in light of scientific knowledge then available, it is not surprising but was, rather, inevitable that public health activities should be focused on environmental sanitation and quarantine for the control of communicable diseases, and that public health practice was visualized as but a defensive mechanism, to be called into play in emergency.

But the situation did not remain static, for there was an immediate expansion of bacteriological knowledge and a strengthening of the epidemiological armamentation for analysis of the mass phenomena of disease and for their control. Further, it is to be noted that the advances made and the contrast between public health conditions and practices of three-quarters of a century ago and now do not relate to communicable diseases alone. Nor is the increase in scientific information limited to growth of knowledge in that field. In extending the bounds of knowledge and in the application of it, the resources of diverse disciplines and sciences, and even of the arts, have been utilized and coördinated: biology, botany, chemistry, dentistry, education, engineering, mathematics, medicine, nursing, pharmacology, physics, physiology, psychology, and others including administration.

Public health practice, on its part, has applied this newer scientific knowledge in fields whose boundaries are so broad that their limits are not yet defined. The prevention of disease is emphasized as an essential for the public health, but it is also recognized that the restoration of health to those who are sick is a matter of public health concern. Any disease or factor that is causing a considerable mortality or morbidity is one of which public health practice must take cognizance. Thus the degenerative diseases, cancer, or

even accidents, present public health problems. Also, in addition to its more or less conventional duties, public health practice has found itself bearing a responsibility in industrial hygiene, in the nutritional status of the public, in the problems of mental hygiene and psychiatry, in dentistry, and in a variety of other health problems ranging from genetics to geriatrics. Many of these involve fundamental and applied research; and as this phase of public health progress is scrutinized, scientific knowledge is recognized as a tap root from which public health advances stem.

In the area of social philosophy and political economy, the situation of today is also vastly different from that of seventy-five years ago. Government could not remain, as it was in earlier days, a vague and shadowy thing of which was expected only the maintenance of law and order and not too much of that. It was inevitable, as population increased and as life became more complex, that society should exercise, through government, a more continuing guidance of community affairs. And as communities developed it became obvious, even to the most individualistic citizen that, by putting some of his money in the form of taxes, into a pool also paid into by others, he could ensure himself communal and individual benefits that it would be difficult to obtain if he acted alone. The number and variety of benefits which the citizen elected to procure in this manner has steadily increased and has come to include funds for the purchase of public health services. But, it is to be noted that, whereas in 1872 such services were paid for and provided on a local basis, the state and federal governments have now come strongly into the field, just how strongly, may be appreciated by looking at 1947 as we did 1872. Here is what we find:

General Grant is no longer in the White House. The population is now

three times as great as it was then, and there are 44 persons per square mile. Los Angeles has reached and passed the 6,000 population which it had as a goal in 1870. Only 14 states have populations less than a million. The nation has become rich, is getting a little gray haired and, in some matters, is on the point of disillusionment. If manufacture, industry, transportation, corporations and labor unions have not passed the stage of infancy, then they are remarkably precocious. The trend toward vesting authority in the federal government is no longer a gentle flow, but a roaring flood and, if a constitutional rock dams up the waters of federal power, it is either by-passed through a new channel, as by the conditioned grant, or is blasted out, as by the Sixteenth Amendment which removed the constitutional prohibition of direct federal tax on citizens, except on a per capita basis.

It is difficult to say whether or not the range of activities supported partly by the federal government, including public health services, will be continued indefinitely. But, as of today, and regardless of whether one approves or disapproves, the trend toward expansion of power of the federal government, the trend toward social legislation, and the vast financial resources derived from the income tax, have made it possible to extend and improve public health services as could not otherwise have been done. This being the case, one must recognize that social and governmental concepts and resources exert powerful influences upon public health practice, and in turn constitute a root from which public health stems.

One must recognize, too, as a sort of compound root, all those elements that go to make up the standard of living of the population: communal and individual standards; the educational level; the habits of hygiene; information on matters of health; food reason-

able in amount and of proper nutritional values; wages that make these things possible and encourage a bit of recreation rather than mental depression from an attempt to make ends meet. And contributing toward the ensurance of this standard of living is the kind and amount of medical care available to each community and to each person in each community.

There is another root of public health and of public health practice that is even more complex and to some extent intangible. This is the professional and personal quality of those practising public health and the wisdom and vision of their leaders. Without these assets, many of the other roots of public health would fail to develop, or would produce a rank growth and bitter fruit.

And now where do we find ourselves in so far as concerns the public health services that we, of this Association, are rendering in our several private or public capacities? Are these services good, fair, or poor? Are they adequate? These questions, I think, may be partly answered by saying that where we have public health services, they are fair to good. But immediately we must qualify this by admitting that one-third of the people of the United States have no local public health service. We must recognize, too, that even where we have such services, there are more fair ones than good ones.

But if scientific knowledge is the root from which stems public health practice, and if society is susceptible to providing funds as a soil in which this practice may grow, what may we do in attempts to ensure that the leaves of the tree shall really serve for the healing of the nations? No person may answer this completely or without error, but I venture to make certain suggestions as follows:

I suggest that the Association and that we as individuals, do even more than we have done, to further the provision of

local health service for every community in the nation.

I suggest that it would further the provisions of local health units for the nation if federal funds in the support of public health work were provided and distributed somewhat as is set forth in Public Law 725, Hospital Survey and Construction Act, wherein needs and plans for complete state coverage must be presented, and systematically implemented. Federal grants to states, in aid of public health work, do not at present ensure similar state-wide development.

I suggest that the mere provision of local health departments for all the nation is not enough; that strong and competent state health departments, with properly related district or regional organizations, are essential; and I express to you the hope that as we gain greater scientific knowledge and organizational competence our federal health services may be better coördinated.

I suggest that this Association and public health workers in general avoid the danger of assuming, and of permitting the public to assume, that merely because a health department is in existence it necessarily meets the needs of the community or state. To this end the Association might well reëmphasize its efforts in support of high professional standards for all categories of public health workers; and emphasize and reëmphasize that even qualified workers, unless in sufficient number, cannot render the public health service that is desirable.

I suggest that there is probable danger in the growing trend toward adding a representative of every sub-specialty of public health to every small health department; that the number of such sub-specialties is becoming alarmingly great, that often they overlap, with confusion to themselves and the public. These things the Association might well

consider in conference with other organizations concerned.

I suggest that, just as the products of research cannot be delivered to the people without proper organization of a sufficient number of qualified workers, so is it impossible for public health organizations to give maximum benefits to the people unless there is ever-increasing scientific knowledge. I therefore urge your continued interest in governmental and philanthropic support of research: research at national, state, and local levels, fundamental and applied research, research in the laboratory and in the field; coördinated and individual research, research by government and by voluntary health agencies; research fellows and fellowships.

I suggest to some governors and mayors that neither old acquaintance-ship with a physician nor obligation to his political friends, constitutes ground for appointing that physician as state or city health officer; that competence in public health matters is not acquired through practice in a private professional capacity, or by having served transiently as an officer in a professional association. To other governors and mayors I offer congratulations on the courage they have exhibited in removing public health from politics, and on the integrity and wisdom they have shown in appointing health officers.

I suggest that to a very marked extent public health work is being reoriented by forces quite outside itself; that society is exerting ever-increasing pressure for new and expanding activities that relate to the public health: pressures for expansion and formalizations in mental hygiene, hospitalization, medical care, the hygiene of housing, research. Some of these undertakings require sound organization, wise administration, and proper coördination with already existing health work and with each other. In all of them it is imperative that those who participate possess

high professional qualifications. The demand that these things be incorporated in public health programs is very strong, and if the public health agencies are unwilling to accept their proper share of responsibilities in these areas, then other agencies, possibly ill-suited, will attempt to meet the need. I suggest that neither a nostalgia for the simpler days of public health work nor a disapproval of some of the implications in a changing social order is sufficient ground for refusing to meet this responsibility. In the public interest, a decision as to what part we shall play should be based upon reason and a sense of reality rather than upon an emotional reaction.

I suggest that the American Public Health Association carry on vigorously its policy of working coöperatively with other organizations interested in the public health; that in relationships with other organizations we emphasize and exploit areas of agreement rather than of disagreement.

I suggest that this Association do all that it is proper for it to do to further the development of sound international

public health organization and professional associations.

I suggest to you that the American Public Health Association is rather a fine organization; that we owe to the Executive Secretary and his staff our deep gratitude for the efforts and genius they have put into the organization of this meeting, and for their unremitting attention to the Association's opportunities and duties.

And now in retrospect and prospect, it seems that we may conclude that the four most powerful influences that have shaped public health affairs in the past, and which will continue to shape them in the future, are advances in scientific knowledge, the direction taken by economic and social evolution, the standards of living of the population, and the quality and availability of medical care and of professional public health workers. Since the founding of this Association, its members have contributed to the acquisition of new knowledge and to its application for the benefit of public health.

May our commendable qualities be enhanced as the years pass.

Puerto Rico Invites Public Health Visitors to Its February Meeting

Dr. Guillermo Arbona, President of the Puerto Rico Public Health Association, San Juan, Puerto Rico, and Nelson Biaggi, Secretary, extended an invitation during the 75th Annual Meeting of the A.P.H.A. in Atlantic City to all public health workers to share in the meeting of the Puerto Rico Public Health Association called for early

February in San Juan. It was hoped and expected that a team of speakers would attend this meeting, and those who would enjoy a vacation at that time of the year in a tropical climate are invited to communicate with the A.P.H.A. office with reference to joining a group who would go and return by steamship or air.

Hospital Relations

The Hospital as an Instrument in a Public Health Program *

VANE M. HOGE, M.D.

Medical Director, Chief, Division of Hospital Facilities, U. S. Public Health Service, Washington, D. C.

A LITTLE more than a year has passed since the Hospital Survey and Construction Act became law. It is safe to assume that most health officers are now familiar with the broad outlines of the national program, which has now progressed to the point where actual construction of hospitals and public health centers will soon be under way.

There is a tendency in most discussions of the Act to speak of it as a hospital program, with less emphasis on its significance from the point of view of public health. Certainly the Act is a major development in the hospital field. For the first time, the federal government has assumed a share of the responsibility for developing a hospital plant capable of serving the normal, peacetime needs of all of our people. For the first time, also, the planning of hospital facilities on the basis of need, as demonstrated by comprehensive surveys, has been adopted as a national policy. And while the principle of federal aid in hospital construction is not new, since it has appeared previously in programs of an emergency nature, the present program is far and away the most comprehensive ever undertaken in this country.

The apparent prominence of hospitals

in the program has no doubt been encouraged by the title of the Act, and by the fact that the term "hospitals" has been stretched, by the magic of legal definition, to include public health centers, so that the latter term is less often used. In the public mind, too, the hospital has far more emotional appeal than the health department. The soldier is more popular than the peacemaker, and the fireman more popular than the building inspector. The man who comes dashing to the rescue after the damage has begun is the hero; the one who prevents it from happening at all is merely a fussbudget.

Nevertheless, it is the intention of both the Law and of its administration that public health facilities shall have an important place. To my mind, one of the most significant aspects of this program is its relationship to the field of public health, not only in the specific assistance which it provides, but also, and perhaps more importantly in the long run, in the basic concepts which it embodies.

First of all, of course, the Act authorizes grants-in-aid to the state to assist in the construction of public health facilities. In doing so, it recognizes the fact that health departments can no longer be tucked away in the basements of obsolete county buildings if they are to do an adequate job. Second, each state is required to draw up an overall plan for the development of public

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 10, 1947.

health facilities as well as for hospitals. It is true that these plans will not necessarily cover the areas which are not now served by full-time health departments. Their development, however, will promote coördinated planning for new facilities, and, it is hoped, will also serve as a stimulus to the extension of present services by calling attention to existing gaps and deficiencies. A modern facility provides strong encouragement for the provision of additional services.

Over and above the immediate practical benefits which health departments will derive from the Act is the implicit recognition of a vastly broadened concept of public health. In recognizing the adequacy of hospital as well as public health facilities as a matter of public concern, in dealing with both in the same legislation, and in vesting the administration of the program in the federal and state public health agencies, Congress has demonstrated its awareness of the interdependence of preventive and curative medicine, and of the importance of both to the national welfare.

This broadened concept is, of course, a logical development, in line with the trend of professional and public opinion. It is a commonplace to say that the field of public health has vastly expanded, and that the health officer of a generation ago would scarcely recognize his profession today. There has been a great increase in the scope of preventive measures, and in the extent to which they are applied. The early diagnosis, isolation, and treatment of cases of communicable disease are recognized as an indispensable element in the control of these diseases, so that individual medical care, in these fields at least, has become accepted as a necessary function of health departments. The recent development of mass attacks on tuberculosis and venereal disease, which do not employ the immunological approach, has brought health departments into in-

creasing contact with the individual patient, and has necessitated a closer working relationship with hospitals and with private practitioners.

Today, the chronic diseases and the degenerative conditions of later life have largely replaced the communicable diseases as our chief public health problems. As the proportion of older persons in our population increases, and as our control of communicable diseases is perfected, this trend will become even more apparent. To date, we have not succeeded in applying mass methods to the control of these conditions, and it appears probable that we shall have to rely, in the main, on the individual approach.

Thus, the line between the field of public health and that of individual hospital and medical care is growing more and more indistinct. Their goals, which have always been closely related, are becoming more and more identical. To an ever-increasing extent, they are using the same methods, employing the same types of personnel, and using the same kinds of equipment. In the interest of efficiency and of better service, closer integration of hospitals and health departments is being urged by leaders in both fields.

As we have noted, the Hospital Survey and Construction Act implicitly recognizes this situation. It encourages the integration of the two fields to a certain extent, since it gives the same agency the responsibility for planning facilities to serve both purposes. In practice, we are going one step further, and encouraging the inclusion of health department facilities in hospital buildings where this appears desirable and practicable. This, we hope, will eventually lead to the development of the truly integrated type of facility which can best serve the needs of public health today and in the future—the community health center, in which preventive and curative medicine are joined

in a broad and unified program, designed to serve the total health needs of the total population.

Such an integration, of course, cannot be brought about by a wave of the legislative wand. The problems of integration, particularly in view of the number of hospitals which are privately controlled, are much too varied and complex to be solved by national legislation, or by state legislation either for that matter. These problems can best be solved by voluntary working relationships between the individual organizations and institutions concerned.

We are amply justified, then, in speaking of the entire hospital survey and construction program as a public health measure. Our hospitals, even though privately owned or operated by other governmental agencies, are essential instruments in any broadly conceived public health program.

If we accept this concept, we must accept also the responsibility for taking an active and informed interest in the development of adequate hospital facilities, whether or not we are directly concerned in the formal program. It may be appropriate, therefore, to review the techniques which we have found to be necessary in carrying out the purposes of the Act.

First of all, there must be a careful study of the need for hospitals and health centers in relation to the extent of the problem of medical care, the requirements of preventive medicine, and the preservation of the health of the community, the area, and the state as a whole. These studies are now being conducted in all of our states and territories, by state agencies appointed for this purpose. An adequate study requires the services of experts in many fields—hospital administration, general medicine, public health, hospital architecture, economics and finance. It also requires the aid of community organizations, professional associations, and

official and voluntary agencies concerned with hospital and medical services. It involves not only the assembling of data on population, incidence and prevalence of disease, economic status and existing facilities, but also expert evaluation of the problems of providing adequate services.

With the aid of the data thus assembled, the state then proceeds to develop a master plan for hospital and health center construction, to serve all areas and all population groups. Naturally such a plan will go far beyond what can be accomplished right away. Selection will be necessary; and this is provided for by the setting up of a priority list of projects.

Over the past year the states have made remarkable progress in this direction. As of today, more than half the states have evaluated their health assets and completed long-range plans for their betterment.

The Hospital Survey and Construction Act sets forth certain standards as to the number of beds which are to be considered adequate for planning purposes. For the state as a whole, the plan is to provide $4\frac{1}{2}$ general hospital beds for every 1,000 people, 5 beds in hospitals for mental disease, and 2 in hospitals for chronic disease. Facilities for tuberculosis patients are to be planned on the basis of $2\frac{1}{2}$ beds for each annual death from this disease, averaged over a period of years. One public health center is to be planned for every 30,000 people, except that sparsely settled states may provide one per 20,000.

Tuberculosis, chronic, and mental disease hospitals may be planned on a state-wide basis. However, like general hospitals, in order to fulfil their mission they should be near the people they serve. General hospitals are best planned on an area basis, area meaning the logical service area of an existing or proposed hospital center. In the

base area, in which the most highly specialized services are available, the ratio will be at least $4\frac{1}{2}$ beds per 1,000. Intermediate and rural areas will plan for fewer beds, with the excess allowed allocated to the larger centers upon which they depend for specialized care. By planning hospitals according to areas, it is possible to incorporate them into a coordinated hospital system, through which the smaller hospitals can receive services from the larger institutions and refer patients to them when necessary.

When the state plan is completed, it is submitted to the Public Health Service, where it is reviewed for conformity with the requirements of the Hospital Survey and Construction Act before approval. Once the plan has been approved, the state agency must determine which communities are ready and able to go ahead with specific projects.

If—as will probably be the case—applications are received for more hospitals than can be aided from the state's allotment of federal funds, the question of priorities becomes of primary importance. The state plan will assign priorities to the various areas of the state, top priorities being given to projects for which the relative need is greatest, those in rural and low-income areas. As the program progresses, the states will review their plans at intervals, reevaluating the priorities.

Recruitment and training of personnel is another necessary technique for reaching our basic objectives. Our present hospitals are hampered by a lack of personnel of many kinds. The effective use of additional facilities will be sharply limited unless personnel training proceeds apace.

Essentially, there are three lines of attack on this problem. First is the expansion of training. Second is the efficient utilization of the personnel we have. Third, and of basic importance,

is the question of salaries, particularly for nurses. Competent personnel cannot be persuaded to enter any profession in large numbers unless the compensation bears some relationship to the time, effort, and money expended in training. These problems are, of course, outside of the scope of the official program. They are, however, vital to its ultimate success, and we are actively interested in discovering effective solutions.

Another important technique in this program is the use of demonstrations and consultation. We have built up a staff of experts to assist the states in planning. Consultants have been placed in the Public Health Service District Offices throughout the country. They are the key people whose primary function is to interpret the program to the states and, in turn, to keep the central office informed as to the needs and problems of the states. In some instances, they are also available to help the state staff in getting its program under way. Similar assistance is needed within the states, and should be provided by the state agencies to communities.

The central element in the structure—the technique which makes possible the realization of the program—is, of course, the use of federal grants-in-aid. The principle of grants-in-aid to the states for health purposes is now well established; it has served well in such programs as those for developing general health services, control of venereal disease, and tuberculosis control, and it is now being applied to industrial hygiene, cancer control, and mental hygiene. All of these programs have in common the purpose of stimulating and assisting the development of health services by the state and communities. Enough funds are provided to make it worth while for the states to participate. The states, however, provide enough of the financial support so that they retain

the major responsibility and the ultimate control. Local responsibility is essential since the actual work must be done in the state and in the community, by people familiar with local needs and problems.

The hospital program involves grants-in-aid for two purposes—for survey and planning activities, and for construction. Three million dollars is authorized by the Act for surveys, the money to be allotted according to population. For construction, \$75,000,000 a year is authorized for a 5 year period. These funds are allocated according to a formula which gives larger amounts per capita to the lower-income states. In each case, federal funds may be used to cover only one-third of the total costs; in other words, each federal dollar must be matched by two dollars from other sources. Thus, if Congress provided the maximum amount for the 5 year period, the federal funds would amount to \$375,000,000. When fully matched by non-federal funds, the total amount available for construction would be \$1,125,000,000.

Instead of directly appropriating funds for construction, the appropriations Act for the current fiscal year sets up a new arrangement which makes \$75,000,000 available for the first year of construction. This arrangement permits the Public Health Service to enter into a contract for each approved project; this contract becomes a federal obligation, and the funds are then appropriated by Congress.

The need for health education, in the broadest sense, has been apparent throughout this discussion, and therefore should be given separate consideration as one of our fundamental techniques for developing the hospital program.

The major part of the health education program will be carried on either through the state agency or in close coöperation with it. The Washington

office works to some extent with newspapers and magazines, and develops coöperative programs with other government agencies and national organizations. But its chief concern is to assist the states and communities in developing their own programs, geared to local needs and timed for maximum effectiveness.

Health education in the hospital program has served definite objectives. First of all, it must be directed to the general public, showing them the value of hospitals and; in many cases, how to organize and plan to obtain them. State and local health departments, professional associations, civic organizations, and community leaders occupy key positions in this work.

Another purpose of health education is to persuade people to make use of hospital facilities. Many of us today forget that the tradition of the pest-house lingers on in the minds of many people. They regard the hospital as a place in which to die, and therefore to be avoided. Education and experience will be necessary to correct this. Another goal of this program is to promote planning for hospitals in rural areas where the need is greatest. And still another point concerns the general practitioner. The now critical shortage of doctors in rural areas must inevitably become still more critical unless and until facilities are provided in which they can properly carry on their practice.

Research is another of the basic techniques which must be used in a continuing program such as this. We must seek better methods of determining hospital needs. We must develop better ways of building hospitals and of operating them. We must improve our methods of training personnel. We must develop better methods of financing hospitals and health services. We must seek to integrate research activities in all phases of hospital planning

and to make this information available without delay.

Then, there is the technique of legislation. When public funds are expended and when the public welfare is affected, laws and regulations are necessary to protect the public interest. In addition to the basic Act, much state legislation has been required to permit participation in the program. Such legislation must be wisely and carefully drawn up if it is to achieve its purposes.

Coöperation with nonofficial agencies is another cardinal principle in the hospital program. In framing the basic law, Congress sought and weighed the views of organizations and individuals with wide experience in all aspects of the problems involved. In drawing up the regulations, the Surgeon General was assisted by an 8 member Federal Hospital Council, and by an advisory committee composed of 40 expert consultants. Similar advisory councils have been set up by the states themselves. Many nonofficial agencies are represented on both the national and state advisory committees.

A final technique which must be used by any group conducting a long-term program, is that of periodic review and self-evaluation. The Federal Hospital Council meets with the Surgeon General at intervals for this purpose. In the District Offices of the Service, and in the state agencies, the program will be reviewed each year before budgets and plans are submitted.

As you have seen, these techniques are somewhat arbitrarily defined. They could be further subdivided and reshuffled in various ways. Nevertheless, all of them are essential if we are to achieve our primary objective—not simply to build hospitals and health centers, but to plan, build, and organize them for maximum effectiveness in im-

proving the health of the people in every community in the nation.

As I remarked at the outset, the program is now in its second year of operation. The survey and planning phase, to which the first year was devoted, is now drawing to a close. Several preliminary applications for grants for the construction of individual projects have already been received; and complete applications, ready for final approval, will arrive very shortly. Thus, actual construction work should be under way in some areas before the end of the year.

Once the state plan is approved, the way is cleared for action. What happens from there on is primarily dependent on local initiative. Specific community needs must be studied; community support must be obtained; detailed plans must be worked out to meet local needs; and arrangements must be made to finance both the sponsor's share of construction costs and the total cost of maintenance and operation.

Now in closing I should like to emphasize that this program opens up a vast new field in public health. Both the hospital construction and licensure programs are new and greatly different from traditional public health activities. Thus, successful administration will require new concepts, new skills, and new approaches. Hospitals from their beginning have grown up in the tradition of community service and autonomy. These traditions cannot and should not be broken. Rather the official agencies must learn to work within them. Once the hospitals are convinced that government is their friend and servant and not their master, the way will be open for effective coöperation. Only through effective coöperation of all concerned can our goal of adequate health services be achieved.

Hospital Relations

Hospital Planning in New York State *

JOHN J. BOURKE, M.D., M.P.H., F.A.P.H.A.

Executive Director, New York State Joint Hospital Survey and Planning Commission, Albany, N. Y.

THE report of the Commission on Hospital Care, *Hospital Care in the United States*,¹ emphasizes the fact that the hospital situation is never static. Improvements in treatment methods, development of new technical equipment and advances in medical science require continuous alertness in hospital planning. The development of an economical, effective and coordinated hospital program demands ceaseless study by the various medical, hospital and health service interests.

A group of experts on hospital care and related activities would find little difficulty in mapping out a broad and comprehensive hospital plan for an undeveloped area; however, to be realistic, any state hospital planning agency must give considerable attention to the developments which may have preceded the present planning stage, especially since such developments usually represent varying interests and aims, both altruistic and vested.

Because of the multiplicity of interested individuals, professions and groups at the state and community levels, hospital planning in New York State has been organized in a democratic manner to allow for full participation of these many interests in state, regional, and community conferences.²

ORGANIZATION ON THE STATE LEVEL

The new Federal Hospital Survey and Construction Act recognizes the need, and requires a single state authority for hospital survey and planning purposes. Unlike a majority of the states, where the departments of health have been designated as the state authority, New York State has appointed the Joint Hospital Survey and Planning Commission, composed of the State Commissioners of Health, Social Welfare and Mental Hygiene, with a member of the Legislature, familiar with hospital administration and health problems, serving in an advisory capacity. This has seemed advisable because, in addition to the Department of Health, the Departments of Mental Hygiene and Social Welfare have considerable responsibility for the administration of services related to the hospital field.

The regularly scheduled monthly meetings of the Hospital Planning Commission have been productive and have made it possible to avoid difficulties and misunderstandings which might have arisen had the responsibility been placed in any one state department.³ In addition, close working relationships have been maintained with the state post-war public works planning activities throughout the planning period.⁴

A State Advisory Council of 25 members, appointed by the Governor to assist the Commission, includes representatives of the hospital trustees

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 10, 1947.

and superintendents, rural and urban physicians and nurses, the medical schools, public health and public welfare officials, Blue Cross Plans, agriculture, labor, and industry. Urban and rural, public and voluntary, and religious interests are also included.

PLANNING ON THE REGIONAL AND LOCAL LEVEL

In 1946, the New York State Commission to Formulate a Long Range Health Program⁵ recommended a regional approach for hospital planning in New York State, as a result of its own studies, the proposals of Mountin, Pennell, and Hoge in 1945,⁶ studies of the Planning Committee of the Medical Society of the State of New York (1945),⁷ conferences with the deans of medical schools, and experiences in this country and in England. The specific boundaries for the 6 provisional hospital planning regions and their subdivisions were determined on the basis of location of facilities, population distributions, marketing practices, and other factors. The regions, which include 6 to 16 counties and populations ranging from 850,000 to 1,500,000 persons, each have a focal point or primary center with at least one medical school and one teaching-type hospital. Each region is further subdivided into a primary or base area, secondary or intermediate areas, and rural areas.

Ideally, political boundaries should be disregarded in the development of such hospital service areas but, from a practical viewpoint, it was necessary to adopt county lines as boundaries of these areas for statistical and legal reasons, among others. However, county lines should not and will not influence or restrict the flow of patients seeking hospital care.

Consistent with this approach, conferences were arranged in each of the 6 regions to include representatives of the many agencies concerned with the

establishment, operation, support and use of hospitals. This brought the state-wide survey and planning for hospitals closer to the local communities and provided an opportunity for local individuals to participate in the overall development of plans.

At each of these meetings, competent people in the hospital and related fields presented their problems and viewpoints. Their subjects included an appraisal of state and local responsibilities, the aims of federal and state legislation and the opportunities for aid in financing and planning. There was discussion of the content and scope of the proposed hospital survey; of the problems of meeting hospital needs in rural areas, small cities and the primary centers; of the relationships between community hospitals and the larger urban hospitals; of the influence of Blue Cross and Blue Shield Plans on hospital service; of the role of the medical schools and teaching hospitals in a coordinated hospital program; of the relationship between hospital, public health and public welfare services; and of the opportunities of sound planning on a regional basis.

Each of the preliminary regional conferences elected a Regional Hospital Survey and Planning Council and designated a secretary, competent in hospital administration, to serve on a state-reimbursement consultant basis. It is interesting to note that the chairmen selected for 5 of the 6 Regional Councils are prominent businessmen.

These Councils, and their executive committees (established in 1946), have continued to serve in the completion of the hospital survey and in the development of the master plan for New York State.

To avoid duplication, the Hospital Council of Greater New York, which has been actively engaged in hospital planning for the City of New York since 1938, was designated as the clear-

ing house for the state work in New York City, with the state subsidizing a portion of its pay roll. Similarly, the State Hospital Commission has cooperated with the Council of Rochester Regional Hospitals which has undertaken a regional hospital plan under Commonwealth Fund auspices.

Briefly, the regional plan of organization has seemed a desirable device: (1) to provide a decentralized method of completing the hospital survey, (2) to return the survey findings to the localities, (3) to appraise existing local hospital facilities, (4) to secure regional recommendations on need for additional hospital facilities and for developing a system of priorities to guide the allocation of federal grants-in-aid, (5) to avoid expensive duplication of facilities, (6) to utilize the 4 medical teaching institutions outside New York City in improving facilities for medical, public health and nursing education, and (7) to develop a coordinated hospital plan for each region and, therefore, for the state.

THE STATE-WIDE SURVEY

With some modification, primarily the deletion of the financial section, the Schedule of Information, developed and recommended by the Commission on Hospital Care, was utilized in securing detailed information from all of the hospitals in New York State.

A somewhat unique procedure was adopted in securing the field data from the individual hospitals. A competent hospital administrator, selected from the primary and each of the intermediate hospital service areas of each region, met with the individual hospital superintendents within his service area to facilitate the completion of the inventory schedule. Subsequently, each of these representatives reviewed his completed schedules with the secretary of his regional council so that the latter might ascertain the accuracy of the

reports and be informed as to the structural organization and service details of each of the hospitals in his region. The schedules were then edited and reconciled with existing state records by the Hospital Planning Commission and sent to the American Hospital Association for coding, punch card preparation and preliminary tabulations.

By having local individuals participate in the fact gathering, the executive committees of the various regional councils were better able to classify their facilities as suitable or unsuitable and to make recommendations for new hospitals, expansion of existing hospitals, and replacement of obsolete plants.

PLANNING STAGE

The staff of the State Hospital Planning Commission assembled, with the help of the several departments concerned, information covering vital statistics, social, economic and other factors for each of the hospital service areas. These data were then made available to each of the regional councils to guide them in the development of local plans.

Utilizing the birth-death ratio formula,⁸ it was possible to estimate the general hospital beds needed to accommodate peak loads. However, it was not possible to develop a formula for the allocation of general hospital beds from rural and intermediate areas to the primary and secondary hospital centers. Therefore, in determining allocations, the factors considered were those of residence of patients treated at the individual hospitals, as reported in the hospital survey, together with social, educational, and economic data which might have an effect upon the establishment and growth of hospitals. With this information before them, the regional councils then discussed and revised the estimates prepared by the state agency.

Caution was exercised in appraising hospitals as to suitability or unsuitability for long-range planning. Conferences of the staff of the Hospital Planning Commission, the area directors and hospital inspectors of the State Department of Social Welfare, and the regional secretaries made preliminary appraisals. In these evaluations all existing hospitals, or portions thereof, were considered unsuitable if they presented definite fire hazards, were obsolete structures or were housed in non-fire-resistive converted dwellings. In certain instances, hospitals were classified as unsuitable because of their very small size which made them uneconomical to operate and difficult to staff. However, in some instances where these smaller hospitals were of sound construction, it was recommended that they expand to at least 50 beds. These appraisals of acceptability were then reviewed by the executive committees of the respective regional councils.

Keeping in mind the locally planned hospital projects, the regional councils formulated recommendations for the state agency as to the size and, in some instances, the location of new hospitals, the expansion of certain hospitals, and the replacement of all or part of obsolete and small plants.

In addition, the regional executive committees adopted resolutions embodying a number of broad principles for regional and state-wide planning, such as:

1. That, except in rare, isolated geographical situations, the minimum size for rural and small urban community general hospitals should be set at 50 beds. The minimum size for new general hospitals in the primary centers should be 150 beds, and in the secondary centers 100 beds.

2. That plans should provide for closer working relationships between full-time public health departments and general hospitals and, where possible and desirable, arrangements should be made for housing health departments in or adjacent to general hospitals.

3. That formal working relationships or affiliations between rural and small urban hospitals and the secondary hospital centers and primary teaching-type hospitals are recognized as desirable for the provision of special diagnostic, consultative, and treatment services, where needed, and for the encouragement of medical and nursing education programs.

4. That chronic disease hospital facilities should be provided as an integral part or wing of general hospitals.

5. That specialty hospitals, such as eye, ear, nose and throat hospitals, should not be developed independently but should be encouraged as a service of the general hospital and not established as separate small units.

The regional councils generally agreed that these principles should be considered in the allocation of state and federal funds and that, in developing project priorities for federal grants-in-aid, consideration should be given to the degree of local need, degree of occupancy of existing hospitals, and the type and quality of community service to be rendered.

The eventual master hospital plan for the state will be reviewed and revised by the Regional and State Advisory Councils before final adoption by the State Hospital Planning Commission.

The local appraisals of existing hospitals and recommendations for additional facilities made by the regional councils could not have been attempted and promulgated satisfactorily by a central state agency alone—nor would it have been practical or expedient to do so.

During the coming months, the local communities which are planning hospitals and related projects will have competent and understanding assistance from the regional councils. Many local problems will arise. They should be solved so as best to meet the need of the area. They should be resolved so as to coordinate community initiative and resources and to insure high quality of care and accessibility, at the lowest

cost compatible with the service to be rendered.

RURAL HOSPITAL AND HEALTH PLANNING

Local interest in more adequate rural hospital and health services has increased considerably during the past year and a half in New York State. It has been stimulated by the Governor's program of liberalization for state aid to counties for the establishment of county health departments and by the possibilities of federal grants-in-aid and state aid for construction of hospitals, health centers and related facilities. This interest has been further stimulated by the Regional Hospital Survey and Planning Conferences and by regional farm meetings sponsored by the State Extension Service and farm organizations during 1946, in which the Joint Hospital Survey and Planning Commission and the State Department of Health participated.

As a result of this local interest in rural health and hospital planning, the New York State Department of Health has established a joint committee with the State Hospital Planning Commission for the development of comprehensive hospital and public health services for rural counties. Counties of less than 50,000 population may apply for state aid of 50 per cent of local expenditures toward capital costs of county general hospitals and health centers, and 50 per cent toward the annual operating deficit of such hospitals. Furthermore, since the Federal Hospital Survey and Construction Act will make funds available for one-third of the construction costs of approved projects, and state aid funds absorb half the remaining cost, or one-third of the total, it is possible for rural counties to establish a county state-aided hospital by raising only one-third of the total cost from local sources. This presents an excellent opportunity for

coördinating the services of the hospital, the county laboratory, and the county department of health.

To date, 13 rural counties have requested that surveys be made and plans suggested by the state for the development of comprehensive health and hospital services in their respective areas. In each instance the formal request must emanate from the county board of supervisors. It has been further recommended that similar resolutions be received from the county medical society and other interested groups.

CHRONIC DISEASE CARE

With the aging of our population, it is becoming increasingly important to prevent and lessen the physical, psychological, social, and economic ravages of chronic illness; and, with the many recent and dramatic demonstrations of the potentialities of rehabilitation, this task can well be one of hope, not the despair of the past. Yet, throughout the nation, as in New York State, there is a growing realization that the present facilities for the care of the chronically ill are inadequate.

To alleviate this situation, the Hospital Planning Commission intends to implement the comprehensive program for improving the care of the chronically ill in the state which was recommended to the State Legislature earlier this year (1947) by the New York State Commission to Formulate a Long Range Health Program.⁹ The major proposals inherent in this program are:

1. The provision of a state agency to carry out a program for the care of chronic illness, exclusive of tuberculosis and mental disease.
2. The establishment of a chronic disease hospital center in each hospital region of the state, providing diagnostic, treatment, teaching and research facilities, to serve as a referral and consultation center. Whenever feasible, the center should operate in conjunction with a general hospital and a medical school.
3. The bulk of the hospital care for the

chronically ill should be provided in wings, wards or floors of general hospitals or in contiguous buildings. Such general hospitals should have formal affiliation with the regional chronic disease hospital centers.

4. All medical *and related* institutions caring for the chronically ill should be required to meet minimum standards of facilities and care formulated and published by the state.

5. The expense of care and rehabilitation of chronically ill persons unable to pay therefor in general hospitals *and related* institutions should be shared by the state.

6. Services for the care of the chronically ill in their homes should be expanded by providing home bedside nursing care and house-keeping aides.

MENTAL DISEASE CARE

The scope of the planning for the care of the mentally ill in New York State is illustrated by the fact that improvements and expansion of the state mental hospitals, as part of the State Post-war Public Works Planning Program, will aggregate over \$96,000,000, including the construction of central medical and surgical units at the larger hospitals. These units will make possible complete physical and psychiatric studies of newly admitted patients as a basis for screening, classification, scientifically determining their prognoses and assessing their potentialities for rehabilitation. In addition, there is considerable state-wide interest in developing psychiatric units at voluntary general hospitals for short-term care and study.

TUBERCULOSIS HOSPITAL PLANNING

With the exception of the metropolitan New York City and Buffalo areas, the problem of needed tuberculosis beds is one of redistribution of facilities rather than of new construction. It is believed that this inadequacy can be overcome readily through the new state aid available to local tuberculosis hospitals, especially because of the new and competent state committee on tubercu-

losis which is making a detailed evaluation of all tuberculosis hospital facilities.

HEALTH CENTERS

Perhaps the most pertinent development in health center planning in New York State, and one that has met with wide acceptance in the rural areas, has been the recommendation that space for a health center facility to house the full-time county health department should be provided in each of the county state-aided hospitals planned for rural areas. It should be noted that, because of the geographic characteristics of New York State, the Commission does not generally recommend the establishment of small community health centers with treatment facilities, except in a few isolated areas, and even in these it advocates that the centers be affiliated with larger general hospitals.

With the provision of state aid to cities of 50,000 population or over for full-time health departments, there will undoubtedly be increasing interest in the development of health centers to house these urban departments. This will require considerable study by the State Department of Health and the Hospital Planning Commission. Unfortunately, however, the full development of this latter program will probably be delayed because of the need to utilize initial federal funds to relieve the acute shortage of general hospital beds.

AN INTEGRATED HOSPITAL PLAN

The American Medical Association, in coöperation with the U. S. Public Health Service, has taken a forward and constructive step toward furthering the development of a coördinated hospital system in preparing a short, comprehensive, yet concise pamphlet entitled *Extension of Medical Care Means Better Health for All Americans*¹⁰ for distribution to all physicians. It presents the mechanism by which a co-ordinated hospital system might work

and what it means to the doctor. It points out the two basic principles involved in a coördinated hospital plan based on adequate facilities, namely: (1) "the flow of professional personnel and special services from the large hospital to the small hospital," and (2) "the flow of patients, specimens and records from the small to the large institutions."

Such a system would consist of four types of units—the medical center, the district hospitals, the community hospitals and, in rural and isolated sections, the community clinics. The core of the system, the medical center, would be a hospital connected with a medical school and would have complete teaching, research, diagnostic and treatment facilities. The encircling district hospitals, of 100 to 200 beds, would similarly have well organized services in most of the specialties but not complete teaching and research facilities. The smaller community hospitals, of 50 to 100 beds, would look to the district hospitals for consultation service and, when necessary, would refer patients to them. The community clinic would be a consultation center, with beds only for emergency cases. In addition, it is suggested that public health offices be housed in the hospitals proper, thus integrating preventive and curative medicine more closely.

It cannot be stressed too emphatically that such a coördinated hospital system will be invaluable to all practising physicians, especially those in rural areas and smaller cities. They would benefit from the research and postgraduate contacts at the medical center and the availability of consultation services. Their patients, therefore, would be more likely to patronize local hospitals rather than migrate to the larger, more distant ones, as is now often the case.

This is the approach that has been taken in New York State, whose master plan is being developed by the many

individuals and agencies, both public and private, interested in the problem. It should serve as a flexible guide to local communities in developing better hospital and health services.

However, the task is not only one of construction of facilities. There are immediate problems and others, now unforeseen, are sure to arise. For example, the planning for general hospitals has raised fiscal problems requiring study and conferences, especially because of their increasing operating and per diem patient-day costs. In addition, increasing attention must be given to the establishment of hospital standards and the procurement and supervision of medical, nursing, and other personnel.

The speed with which the aims of the master plan are accomplished will depend on the interest and zeal of the public, the full support and coöperation of the medical profession and hospital authorities and their willingness to work harmoniously with voluntary and governmental agencies. The program is being planned with full appreciation of local needs. Flexibility in planning has been a prominent feature. The results should, therefore, be most acceptable to our co-planners and users of the envisaged facilities—the local citizens.

Finland Needs Technical Books

Arthur E. Morgan of the American Friends Service Committee makes the following plea in behalf of the Helsinki Institute of Technology.

During the war, Finland's excellent and keenly scientific minded Technical Institute (Teknillinen Korkeakoulu) was bombed and totally destroyed. On a recent trip to Finland for the American Friends Service Committee, Dr. Martti Levon, Director of the Institute, said he would welcome gifts of scientific and technical books and periodicals from America. The lack of technical

library facilities is a very serious handicap in the Finns' remarkable efforts for recovery.

It would be a practical act of friendship to a nation that holds America in high regard if Americans should contribute good technical books and periodicals to this library. Such gifts should be marked for the Institute of Technology, Helsinki, and sent to the Legation of Finland, 2144 Wyoming Avenue, N.E., Washington, D. C. The Finnish Minister, Dr. K. T. Jutila, will arrange for shipments to Finland.

Hospital Relations

The Hospital Planning and Licensing Programs in Indiana *

L. E. BURNEY, M.D., F.A.P.H.A., AND
MARTHA O'MALLEY, M.D., F.A.P.H.A.

*State Health Commissioner, Indiana State Board of Health; and Director of the
Division of Hospital and Institutional Services, Indiana State Board of
Health, Indianapolis, Ind.*

HOSPITAL survey, planning, inspection, and licensing constitute new fields of endeavor for most health departments. Two acts passed by the 1945 Indiana General Assembly^{1,2} referable to the above functions enabled the Indiana State Board of Health to develop hospital planning and licensing programs in advance of many other states. We believe that the methods used, the problems encountered, and the results to date may be of interest and possibly of some assistance to other agencies which have assumed similar functions.

We realized from the beginning that both the hospital planning and the licensing programs would bring the State Board of Health into a new relationship with professional groups, particularly hospital administrators, physicians, dentists, and nurses. Therefore, the advice and assistance of such groups were sought and secured in the organization and development of these programs. The members of these associations have been kept thoroughly informed on the developments of the programs in the various stages.

One of the first steps taken preparatory to the survey of hospitals and health centers was to meet with the representa-

tives of the hospital, medical, dental, and nursing associations. At this meeting it was recommended that six regional meetings be held and that members and officials of the organizations concerned attend. These meetings served to acquaint such individuals with the purpose and scope of the survey and afforded an opportunity to discuss the survey form prepared by the Commission on Hospital Care entitled "Schedules of Information." The survey form was mailed to all hospitals and related institutions during September, 1945, and the completed forms were received by March 1, 1946. As was to be expected, our staff members made many field trips in connection with the completion of the survey forms. These were reviewed before being sent to the Commission on Hospital Care for tabulation.

Following the tabulation of the completed schedules, a tentative hospital plan, based on the formulae proposed by the Commission on Hospital Care, was developed with the assistance of an Advisory Hospital and Health Center Planning Council. This Council was appointed by the Governor to work with the State Board of Health in the development of the state hospital plan. The membership of this council is composed of the following:

State Health Commissioner, Chairman	1
Representing the Indiana State Medical Association	3

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 10, 1947.

The development of a tentative state hospital and health center plan enabled the council and the State Board of Health to work out the principles to be followed in preparing the final plan. When the federal regulations³ were received early this year, we adapted our previously developed tentative hospital plan to these regulations. The federal regulations required only minimum standards, thus allowing us flexibility in planning to meet the particular needs of our state. Figure 1 shows in a diagrammatic manner Indiana's proposed coordinated hospital plan.

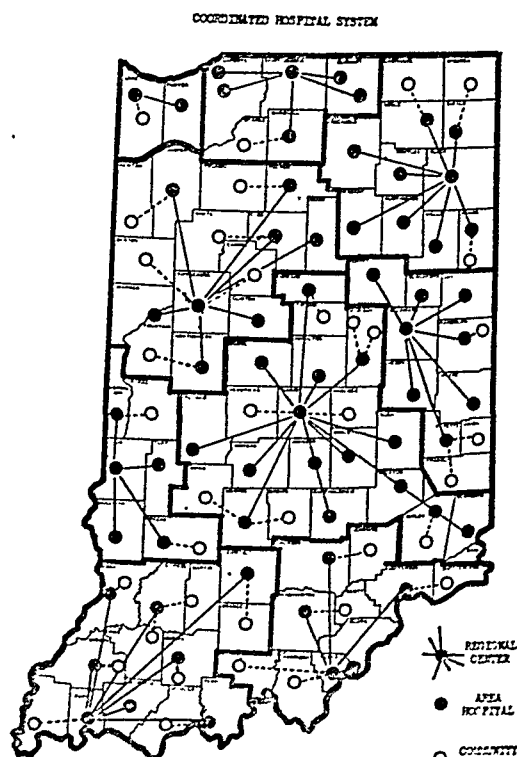

The principles followed in the development of our State Hospital plan⁴ were as follows:

1. The development of a coordinated hospital system on a voluntary basis.
 - a. The base hospital shall include a teaching hospital of a medical school approved by the American Medical Association's Council on Medical Education and Hospitals. This requirement will provide quality services in the various medical specialties and will make available consultation service and postgraduate educational programs for professional personnel in district and rural hospitals. (There is only one center in Indiana—the Indiana University Medical Center in Indianapolis—which meets these re-

quirements. Fortunately, it is located in the center of the state.)

- b. Intermediate hospital areas shall include hospitals that meet requirements equivalent to those established by the American College of Surgeons or the Council on Medical Education and Hospitals of the American Medical Association. They shall maintain high quality facilities and personnel for providing specialized services in the fields of internal medicine, surgery, obstetrics, pediatrics, ear nose and throat, dentistry, radiology, and laboratory, and shall provide training courses for interns or residents. In addition, plans will be made to offer, in the future, specialized services in venereal diseases, tuberculosis, communicable diseases, and psychiatry. The base hospital will provide postgraduate educational opportunities for professional personnel in the area.
 - c. Hospital service areas will be allotted for all existing and proposed hospital facilities of 25 or more beds. This number was chosen because it is conceivable that a facility of 25 beds would increase to a 50 bed hospital.
2. Plan for allotment of hospital beds in the various categories.

FIGURE 1

- a. General hospital beds are allotted on the basis of the federal regulations and the formulae proposed by the Commission on Hospital Care. This, in Indiana, provides approximately 5 beds per 1,000 in the base area, 4.5 in intermediate areas, and 3 per 1,000 in local or rural hospital areas. Community clinics or health centers are planned within a larger hospital service area, with a provision for 1 bed per 1,000 population.

b. The 2 chronic disease beds per 1,000 population are allotted as follows: 1.5 beds per 1,000 population to be constructed as units of local (rural) general hospitals, and the remaining beds—amounting to over 2 per 1,000 population—to be constructed in intermediate
- and base areas as units of general hospitals.

c. One-third of the total mental beds are planned as units of intermediate and base general hospitals, and the other two-thirds are planned in connection with state mental hospitals.

d. Tuberculosis as well as mental units are to be established in connection with intermediate and base general hospitals. All additional tuberculosis beds are planned as units of intermediate and base hospitals. The only new beds to be allocated in county and state tuberculosis hospitals are for replacements of nonacceptable beds. General hospitals, other than those in the intermediate and base areas, are to be permitted to plan

* Ranks are arranged in inverse order. Areas needing financial assistance must have the highest numerical rank.

¹ County has non-conforming general hospital. These four counties are arranged in order of relative need considering existing facilities.

Cities and towns listed under this heading are the name by which the area will be known. Several hospitals and health centers may be located in each area designated.

tuberculosis and mental units, provided trained medical, nursing, and other professional personnel are available to staff them.

- e. Public health centers with administrative offices for public health personnel are provided. These administrative units will be developed wherever possible in connection with hospitals or health centers. Where this is not possible, separate facilities may be planned.
- f. The priority for federal grants-in-aid for hospital construction⁵ was established for every hospital service area in the state on the basis of relative need for hospital services. A second factor to be introduced to differentiate the relative need of areas that do not have any existing hospitals was the distance from neighboring general hospitals of 50 or more beds. A third factor used to separate areas where the relative need was practically the same was the area's effective buying power in relation to that of the state. (See Figure 2 on "A" priority group.)

Indiana's hospital and health center plan, incorporating the above principles, was approved by the planning council and by the State Board of Health early in May, 1947. The plan was then presented to the executive committee of the Indiana Medical Association, to a joint meeting of the licensing council and the Indiana Hospital Association, and to the Indiana Nurses' Association. It was approved in principle by these groups. In addition, the plan was presented to the State and Component Officers of the State Dental Association, to the Indiana Public Health Association, and to the Indiana Economic Council. A description of the plan was published in approximately four hundred newspapers throughout the state. A public hearing on the plan was held on June 9, 1947. There was no expressed opposition from either the professional or the lay groups. The Surgeon General of the U. S. Public Health Service approved our plan in July.

Indiana's 1947 General Assembly enacted legislation⁶ authorizing the State Board of Health to cooperate with

the Government of the United States in the construction or improvement of public and other nonprofit hospitals and to accept and disburse federal funds to carry out this work. Therefore the hospital construction and the planning programs come under the administrative direction and supervision of the State Board of Health. The Division of Hospital and Institutional Services, which was created June 1, 1946, is responsible for administering the hospital and health center plan, resurveying hospitals and health centers, and for developing, in cooperation with the licensing council, the hospital licensing and regulating program.

The Bureau of Sanitary Engineering is responsible for supervising the construction part of the hospital program, for making site surveys, and for the inspection of hospitals in regard to compliance with the environmental sanitation clauses of the general regulations for hospitals.⁷ In addition, personnel from the Division of Health Education and the branch offices of the State Board of Health are participating in promoting the educational aspects of the program. Realizing that an extensive educational program is required to disseminate information and to bring concerted effort to bear on local problems, a workshop conference for health education personnel was held in June of this year. Figure 3 presents the functional organization of the State Board of Health, showing the relationship of the various activities in the hospital program.

The Division of Health Education and the branch offices of the State Board of Health, working with the Division of Hospital and Institutional Services, have disseminated to local areas information in regard to the state hospital and health center plan. They have encouraged local communities to study their public health and hospital problems in order to effect an organization to meet their needs. Our health educators

FIGURE 3

are working with local hospital boards in developing and carrying out educational programs to acquaint the public with the services offered by hospitals and the interrelationship of hospitals and public health programs. Rural medical care committees throughout the state are vitally interested in planning adequate hospital facilities for people in the rural areas.

It is believed that the hospital and health center plan can be promoted through the hospital licensing program. As required under the Federal Survey and Construction Program, an annual survey of the hospital facilities will be made at the time of the annual inspection of the hospitals for licensure.

An act passed by the 1945 General Assembly provides that the regulating and licensing of hospitals shall be administered by the State Board of Health with the assistance of a council. This council consists of 4 hospital admin-

istrators, 1 physician, 1 nurse, a member of the State Department of Public Welfare, and a member of the State Board of Health. The membership, the term of office, and the functions of the council are specified in the licensing act. This is in contrast with the planning council which is appointed by an Executive Order. The licensing council has no direct responsibility for the state hospital and health center plan. Only one person, the Director of the Department of Public Welfare, is a member of both councils. No difficulty has been encountered in having separate councils carrying out the planning and licensing phases of the hospital programs. Since we have relied so heavily upon both groups, this arrangement has proved to be very advantageous. It would have been difficult for one group to have assumed dual responsibilities; also, wider representation in the health field is achieved by this method.

Upon review and approval of the council, licenses are issued by the State Board of Health. If, after investigation and a hearing, the council finds that a license should not be granted, the applicant is so notified. The decision of the council on this matter is final.

The general regulations for hospitals, promulgated under the hospital licensing act, became effective May 3, 1946. There are 41 specific regulations under the four general headings of administration, building and construction, environmental sanitation, and specialized hospitals and specialized services.

Inspections or surveys of hospitals are made by a physician, a hospital consultant nurse, and a sanitary engineer. All hospitals are also studied by the fire marshal. In addition, consultation services are provided to hospitals in general administration, business administration, nutrition, pharmacy, and statistics. It has not been possible, due to the limited staff, to inspect all hospitals prior to the issuing of licenses. Detailed inspection of hospitals under 25 beds have been made.

Following the study of hospitals, complete reports of findings—including the degree of compliance with regulations—are made to the council. The hospital administrator is invited to meet with the council when there is a question of compliance with the regulations. The administrator is informed before the scheduled meeting in regard to any regulations with which he has not complied. He is further advised that the council will wish to know his plans for compliance with the regulations before taking action on his application for a license to operate a hospital.

Administrators and owners of institutions are pleased with the opportunity to appear before the licensing council to express their viewpoints. To date, the action of the licensing council has not been contested in the application of the licensing act.

In hospitals of over 25 beds, meetings are arranged between the hospital staff and our consultants. These meetings are held after the inspection of the hospitals for the following reasons:

1. To discuss any noncompliance with the general regulations for hospitals.
2. To work out jointly plans for compliance with the regulations.
3. To discuss the application of the provisions of the state hospital and health center plan to the individual hospital.
4. To answer any questions that members of the hospital staffs may have in regard to the licensing or hospital construction program.

Those of us who have been working with the hospital planning and licensing programs in Indiana feel that they have definite possibilities for improving public health as well as hospital facilities in Indiana communities. We expect to see an increase in the practice of preventive medicine in Indiana in the next few years through the provision of diagnostic and consultation units in hospitals for the care of ambulatory patients. We believe that the working relationship established between our staff and the personnel engaged in hospital administration will result in more effective public health and hospital programs.

In conclusion, it is our belief that hospital planning and licensing programs are proper functions of a health agency. The administration of such activities has proved to be a healthy, stimulating experience in Indiana.

Hospital Relations

Hospital Services in Saskatchewan *

FREDERICK D. MOTT, M.D., F.A.P.H.A.

*Chairman, Saskatchewan Health Services Planning Commission,
Regina, Saskatchewan, Canada*

ONE of the great problems in hospital planning has always been that of providing services in areas where people are unable to maintain hospitals. We have gone a long way toward overcoming this difficulty in Saskatchewan, where facilities are being planned and developed as part of a general health program, which includes compulsory hospital care insurance for virtually the whole population.

Through spreading costs, such a system not only means that care is provided on the basis of individual need, rather than capacity to pay, but it also means that hospitals can be located where they are needed, because there is payment for every case and because the cost of maintaining a particular hospital does not rest solely on the people whom it serves.

Many contend that health insurance should await great expansion of hospital facilities and greatly increased numbers of health workers. In Saskatchewan, the existence of a prepayment plan facilitates hospital development, while the work of the planning agency, through which control over the quality of services is exercised, assures emphasis on standards of care, and prevents the insurance plan from becoming a payment agency unrelated to broader health objectives.

The province in which we are working

out this coördinated program is typically rural, with a comparatively small number of people, most of whom live on farms and in little communities scattered over a vast area. The whole province of Saskatchewan is almost as large as Texas, but most of the people live in the southern half of the province, in an area as large as New Jersey, New York, and all the New England states combined. This southern part of Saskatchewan, which has a population density of less than seven persons per square mile, is for the most part wheat-growing and ranching country, essentially similar to the Great Plains states.

Eighty per cent of our 840,000 people live in communities of less than 2,500. Only two states, North Dakota and Mississippi, are more rural. There are only four centers in the province with more than 10,000 people; our largest city has a population of 60,000.

In this rural situation, fundamental social and economic factors, in combination with the character of local government, have had marked effect on the development of health services.

There is only one level of local government in the province, the municipal level, county organization never having developed in Western Canada. In addition to the cities, towns, and villages, which are organized separately, the farming districts are divided into more than 300 self-governing rural municipalities. These are typically 18 miles square, following a geometric pattern laid down by early surveyors, and

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 10, 1947.

ordinarily having populations of from 1,500 to 2,000.

For a generation, the municipal unit has been fundamental, not only in the organization of basic public health services, but in collective provision for medical and hospital care. An illustration of this is the well known "municipal doctor" plan, a system of prepayment on a municipal basis which has extended medical care to rural areas where it would otherwise have been unobtainable. Under this tax-supported system, service is ordinarily provided to all residents by a general practitioner on salary.

Experience in solving their immediate medical care problems through direct action of this kind has been highly significant in creating among our rural people not only an awareness of their medical care needs but a demand that broad solutions be worked out by government as rapidly as possible.

Less well known than the "municipal doctor" plan, but equally important in the development of provincial services, is the Union Hospital system. Union Hospital Districts are groups of municipalities—towns, villages, and rural municipalities—which have joined together to establish a special local authority for the purpose of erecting and maintaining a hospital. During thirty years of development, the Union Hospital has become the predominant type of hospital in the province. In the larger towns and cities, there are municipally owned hospitals serving the whole community.

Half of the people in the province tax themselves to provide hospital facilities. Until the beginning of this year, when the provincial hospitalization plan went into effect, many areas also made provision for hospital care for their residents.

The present organization for the administration of health services in the province incorporates within its struc-

ture provision for further development of many of the services previously established by local communities.

The provincial health program is administered by two agencies of government, the Department of Public Health and the Health Services Planning Commission, the directors of which are both responsible to the Minister of Public Health.

The Department of Public Health is responsible for developing and administering a range of public health services similar to those falling within the jurisdiction of state departments of health. In addition, the entire program of mental health is administered by the department, including institutional care. Worthy of special note among the functions of the Department of Public Health are the activities in the field of cancer control. Provision has been made for case finding and treatment at public expense. Moreover, the department conducts an air ambulance service which has demonstrated its value in making the best medical care available to persons in isolated areas.

The Health Services Planning Commission is responsible for the planning and development of health facilities and medical care services. This includes the elaboration of a provincial plan for the development of hospital facilities and the administration of laws and regulations governing hospital standards; the administration of the province-wide tax-supported program of hospital services; supervision of development of medical care services administered by health regions and municipalities; and administration of medical care for groups receiving public assistance.

We have found that the close co-ordination of functions of both the department and the commission is essential in the development of services and facilities. An important point of coördination is the health region, the local jurisdiction established for the

development of both preventive and therapeutic services.

In defining areas to be covered by health regions, as well as in planning the development of hospital facilities, common use is being made of the natural trading area. A thorough study of the province, the distribution of its population, communications, and natural boundaries, has resulted in a clearly defined picture of the distribution of trading areas and trading centers. These centers are being chosen as sites for hospital and diagnostic facilities, as well as centers for the development of preventive functions, to assure accessibility to all residents of the area. The hospital district and the public health district will thus have common boundaries.

A health region is composed of a number of these districts grouped with reference to major trading centers. Specialist services, a more extensive range of diagnostic facilities, and the organization for the administration of preventive services in the region, are being located at the regional centers.

Working closely with the health officer in each region is a regional board, which serves as the board of health and also as the board of directors for any regional program of medical care which may be developed. The regional boards are elected on the basis of population by district health councils which consist of representatives from all municipalities in the area.

Coördination of the functions of our commission and the Department of Public Health in health region development is effected by use of a common Division of Regional Health Services. This division is responsible both for public health and medical care developments in the regions. There is already evidence of the value of such coördination. District activities in the various phases of the preventive program are being based on district hospital centers wherever possible, with health center

facilities being incorporated in hospitals or developed in close relationship to them. Moreover, to an increasing extent, physicians' offices are being provided in district as well as outpost hospitals. We think that district hospitals can provide a base for supplying local practitioners with facilities and equipment essential to the modern practice of medicine, that regional centers should provide specialist and consultant services to the local doctors through development of group practice units, and that these regional groups in turn should depend for consultation and the opportunity for referral upon our two larger urban medical centers.

In our second largest city, Saskatoon, construction is starting on a 550 bed University Hospital. It is to be associated with the College of Medicine, which is being extended from a basic science course to a full 4 year course. Our whole pattern of regionalization of hospitals and health services is being built around the concept of a central teaching institution which in countless ways will raise standards throughout the province.

The principle of an integrated system has been fundamental to our thinking as we have attempted to guide hospital construction.

There are 4,286 beds in non-federal general hospitals in Saskatchewan, or almost 5 beds per 1,000 population. Because our population is widely scattered, a large number of small institutions have developed, and it will probably continue to be necessary for us to have good facilities in a few institutions with less than, say, 25 beds. Some of these, as now, will come within the category of maternity homes, or "doctors' workshops."

While there are many small institutions today, their total bed capacity is not great. If we eliminate our institutions with fewer than 15 beds, we still have 3,771 beds or 4.5 per 1,000 population. Distribution across the province

is somewhat uneven, but the lowest ratio in any region is 3.5 beds per 1,000.

Most of these institutions are administered by public authorities. The idea of municipal governments providing hospitals only for the indigent has never had the same acceptance in Canada as in the United States and Great Britain. All of our Saskatchewan hospitals serve the general population. The importance of public administration of hospitals varies in different parts of Canada: in the West it is the basic pattern, in Saskatchewan it is most important of all.

Out of 66 hospitals with 15 beds or more, 37 are administered by union hospital boards, 8 by other municipal authorities, 16 by religious orders, and only 5 by lay voluntary boards. With the encouragement of the Health Services Planning Commission, there has been a sharp increase in the population coverage and area served by union hospitals. The number of such hospitals has more than doubled during the past two years.

The combination of union hospital development, provincial grants and loans for hospital construction for the past three years, and the general demand for additional facilities, has resulted in a substantial increase in hospital accommodation. In addition to the 4,286 beds actually in use, there are 867 under construction and 1,014 more in the planning stage. When these facilities are completed, we will have 7.3 beds per 1,000 population, exclusive of those in tuberculosis, mental, and federal institutions. This ratio, which includes chronic disease facilities being developed in general hospitals, is, we feel, amply justified and realistic in our highly rural province.

One of the principal factors leading to the demand for expanded hospital facilities is the existence of our hospital care insurance plan. This program, the operation of which is a major admin-

istrative function of the Health Services Planning Commission, has been in effect since January 1, 1947.

It covers about 93 per cent of the provincial population, or over three-quarters of a million people. Public assistance cases receive benefits but are exempt from payment, their taxes being paid by the agencies responsible for their maintenance. The Plan covers everybody except those already provided for by federal or provincial programs for special groups or special conditions. Participation is compulsory except in the remote areas of the Far North where a few thousand trappers and fishermen are being included on a voluntary basis.

The Hospital Services Plan is financed by an annual personal tax of \$5 per capita, with a family maximum of \$30. The tax is collected through about 1,000 municipal offices, a commission being paid for the service. Payments are kept in a special fund to reimburse hospitals on the basis of approved accounts. This fund is supplemented from general provincial revenue, to the extent of approximately 40 per cent of the total cost of the program, the \$5 personal tax making up 60 per cent.

Benefits provided under the Plan include public ward or minimal accommodation, general nursing care, use of operating and delivery rooms, most drugs and medicines in general use, and a range of special services including x-ray and laboratory examinations, radium treatments and physiotherapy. The extra cost of private or semi-private accommodation is paid by the patient. The most important limitation on the service is the exclusion of outpatient treatments.

There is no limit on the length of stay in Saskatchewan hospitals, medical necessity being the sole criterion. There is no restriction on the choice of hospital, payments being made to approved hospitals anywhere in the world. How-

ever, payments for care outside the province are on what amounts to an indemnity basis, and cover only 60 days for any individual in any year.

During the first six months of operation more than \$3,000,000 was paid to Saskatchewan hospitals, in settlement of about 10,000 accounts per month. The average payment per case has been \$48, and the average length of stay about 10 days. This represents about 160 cases or 1,600 days per 1,000 covered population annually, surely a far truer measure of real need than the lower ratios characteristic of voluntary plans, with their limited benefits and selective coverage.

Payments to hospitals are made on the basis of inclusive rates determined according to a schedule of points for assessing the relative adequacy of their facilities. The number of points allotted each institution is determined by our Division of Hospital Planning and Administration by means of individual inspection.

Experience has shown that payments made to hospitals on the basis of their point rating have not been closely related to the cost of operating individual institutions. With the lack of adequate cost data, it was inevitable that the initial payment system should be arbitrary. However, studies are now in progress which should result in the development of a revised payment system for 1948. In the meantime, hospitals—chiefly small institutions—with legitimate operating deficits, are receiving supplemental payments.

Analysis of financial statements has been facilitated by the development of a compulsory uniform accounting system for all general hospitals in the province.

The point system of payment has unquestionably led to improvement in hospital facilities and services, 91 institutions having increased their point allotments since the beginning of the year.

It has been possible for us to guide hospitals in relating their purchase of equipment to actual needs. However, lack of funds, associated with the complete absence of federal support, has made it essential for us to limit our grants for hospital equipment to cases of greatest need.

Similar considerations prevail with respect to grants for hospital construction. Making a comparison on a per capita basis with grants being made under the Hospital Survey and Construction Act, our provincial construction grants amount to approximately two-thirds of those made in the states by the federal government in this country. While we are handicapped by a lack of funds, and are forced to maintain the general principle of local responsibility for capital construction, persuasion is accomplishing a great deal in the direction of our overall objectives.

It is hard to overestimate the value of the prepayment plan in our program of developing a network of functionally related institutions. Not only does the insurance plan make the necessary provision for maintaining hospitals; it fosters the improvement of facilities and it supplies us with a continuous body of data respecting hospital utilization.

Our statistics of hospital use are still in a rudimentary stage, but they already make possible a continuous province-wide study of such factors as the amount and character of hospital service, length of stay and diagnosis by type of institution, the distribution of charges, the relative need for additional facilities by regions, and the efficiency of use of existing facilities.

A good illustration of the use to which data from the hospitalization plan are put in our hospital planning may be found in our study of long-stay cases. Hospitals are required to file reports on all cases hospitalized for more than 3 weeks. These reports, which give social and economic data as well as information

as to sickness, provide us with material for studying the need for facilities for the chronically ill. This information is also an essential element in the co-ordination of our program with social welfare services.

The pattern for the development of hospital services in Saskatchewan is already well established.

Many problems remain unsolved. The

most pressing of these relate to the improvement of standards of service, personnel training, and the development of a satisfactory method of payment. But we are confident that we have established a sound basis for planning, which would have been impossible without full acceptance of the principle of spreading the costs of hospital care across the entire community.

1948 American Medical Directory

The 18th edition of the *American Medical Directory* is in preparation by the American Medical Association. About November 15, a Directory Card was mailed to every physician in the United States, its dependencies, and Canada, requesting the information to be used in the new *Directory*. It asks that physicians fill out and return these cards promptly even though no change

has occurred in any of the points of information requested and even though a similar card has been sent in recently.

Physicians who have not received one of these information cards should write immediately to the Directory Department of the American Medical Association, 535 North Dearborn Street, Chicago.

Comparative Epidemiology of Poliomyelitis in Certain California Cities*

W. McD. HAMMON, M.D., DR.P.H.

The School of Public Health and the George Williams Hooper Foundation for Medical Research, University of California, Berkeley and San Francisco, Calif.

WHILE studying the epidemiology of poliomyelitis and encephalitis in the field in certain of the western states, the author became impressed by the apparent excessive rates for poliomyelitis in Kern County, California, in contrast to those in certain other counties in the same and adjacent states. However, it appeared to be impractical to make even relatively accurate comparisons because of the difficulties encountered in the differential diagnosis of poliomyelitis and encephalitis in the San Joaquin Valley (Kern County, California) and because of obviously poor reporting in certain other counties. A search was made therefore, for other more suitable study areas with apparent differences in rates. Los Angeles and San Francisco, from a superficial examination and common "reputation" appeared to be suitable for contrast. The Oakland-Berkeley area near San Francisco, and San Diego, relatively close to Los Angeles, were selected to be included in the study because, though each was near the city primarily selected, marked climatic differences existed. Human encephalitis of the Western equine and St. Louis type had not been recognized as occurring in any of these cities. In the absence of encephalitis of these

types, it was considered that in all probability differential diagnosis had not been unusually complicated, and that morbidity reporting had not been unusually unreliable. All these cities had had city health departments with full-time staff, recording poliomyelitis since 1920. Thus, from 1920 to 1945, records were available for examination.

An attempt has been made to demonstrate whether recorded differences in poliomyelitis mortality and morbidity are real or only apparent; if real, to analyze the differences in an attempt to shed further light on the epidemiology of the disease.

Since the four urban areas under consideration are sufficiently familiar to most members of this audience, little description will be offered. San Francisco, Oakland, and Berkeley are in "northern" California (north of the Tehachapi range). San Francisco lies on a peninsula bounded on the west by the Pacific Ocean, on the north by the Golden Gate Strait, and on the east by San Francisco Bay. A range of low hills extending from north to south divides the city. The bay separates San Francisco from Oakland and Berkeley to the east, by a distance of about 7 miles. Oakland and Berkeley are contiguous. The hills of San Francisco partially shelter the East Bay cities from the ocean breeze and from the banks of fog that frequently form over the ocean and drift over San Francisco. Los Angeles, about four hundred miles

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 10, 1947.

Aided by a grant from the National Foundation for Infantile Paralysis, Inc.

to the south, lies slightly (10 to 15 miles) inland, while San Diego, approximately 100 miles south of Los Angeles, is built directly on the coast about San Diego Bay.

Differences in the mean maximum and minimum monthly temperatures can be noted from Chart 1, where the same 5 year period is plotted for each. In all instances for the periods shown, recordings were made from near the heart of the city.

Mean maximum temperatures in the summer are highest in Los Angeles, but it will be noted that the mean minimums in the same months are highest in San Diego. The *mean* monthly temperature during summer (not charted) is two to three degrees higher in Los Angeles than in San Diego. It may also be noted that the extremes between summer and winter temperatures are greater in Los Angeles than in San Diego and San Francisco, but the swings are about the same as those of Oakland and Berkeley.

Variation from mean minimums to maximums in the same month (night and day changes) are greatest in Los Angeles. The months of highest summer temperature are either July or August in both southern cities, but the mean for August over a period of many years is the higher in both areas. Peak temperatures in the northern cities are slightly later.

The northern cities, it may be readily observed, have a distinctly cooler climate. San Francisco, by the width of the plateaus on the graph (March through October) and the slighter change from winter to summer, may be noted to have a much more even climate than any of the other cities. In fact, it is quite commonly stated that San Francisco has neither summer nor winter. The seasonal changes are decidedly more distinct in the East Bay.

The age distribution of the population below twenty years of age, prior to the war, was quite similar in all areas,

CHART 1

Maximum and Minimum Mean Monthly Temperatures
1925-1929

but during and after the war the changes were not uniform. San Diego for example, showed an increase in the age group 15-19 (San Diego Naval Station), while the population in this age group decreased in all other areas.

All four urban communities contain larger numbers of orientals and smaller numbers of Negroes than do most eastern cities, but in no city does the oriental population exceed 3 per cent, or the Negro population 5 per cent. The southern cities contain a higher population of the Mexican, Hawaiian, and Philippine peoples than do those of the north, but no exact figures have been obtained for these.

Both San Francisco and Los Angeles furnish clinical teaching material for two medical schools. Thus, physicians have a high standard of medical, diagnostic acumen, and an interest in co-operation in disease reporting. Berkeley now contains a school of public health, has had one previously, and has for many years had, in the University of California, an active Department of Public Health, and a Department of Public Health Nursing, each with medical and professional faculty partly derived from the East Bay cities. San Diego is not a medical center for civilians, but is an important naval medical center. The Navy's influence on civilian doctors, however, is difficult to evaluate.

All four urban areas conform to the uniform state requirements for poliomyelitis reporting. Until 1927, only paralytic cases were reportable; from then till 1934 non-paralytic cases in the family of a paralytic patient were included, and, since 1934, all cases of poliomyelitis have been reportable.

Data used in this study were collected from the files of the California State Department of Public Health through the kind coöperation of Miss Ida May Stevens of the Division of Communicable Diseases. Cases and deaths have been reallocated to their

place of usual residence, so that rates are not increased in the medical centers by importation of cases from rural and other nearby urban areas. Only cases reported as having occurred within the city limits are included. Army and Navy cases and deaths have been completely excluded since information for reallocation could not be obtained. Because for San Diego the only population data available for 1945 (used for making estimates from 1941 to 1944) included a large Naval population, the rates for San Diego in these years must be assumed to be low.

MORTALITY

In Table 1 may be found the mortality rates per 100,000 population by years for the four areas 1920-1945, and in Table 2 the means and medians for the same period. It will be noted that San Diego has the highest median and mean mortality rates and, in descending order, are Los Angeles, Oakland-Berkeley, and San Francisco. The difference between the first (San Diego) and the last (San Francisco) is over twofold in the means, and threefold in the medians. As pointed out above, San Diego rates have been reduced somewhat by excluding Navy deaths; so that the differences may be even greater than shown. Since the completeness of reporting of deaths from this cause can be considered to be relatively the same in all of these cities, and since the diagnosis of fatal poliomyelitis usually presents the least difficulty of any type of the disease, these rates probably represent a relatively true reflection of poliomyelitis mortality.

MORBIDITY

Median and Means for Total Period—

When the median morbidity rates (Tables 1 and 2) are examined for the period of 26 years it is noted that the cities hold the same order as for mortality, San Diego highest and San Fran-

over the radio urging all New Yorkers to be vaccinated without delay. Vaccination clinics in the Health Department headquarters building, in all Health Department health centers, and in the city hospitals were kept open day and night, seven days a week.

Two hundred and fifty thousand individual doses of smallpox vaccine were available for immediate distribution by the Health Department laboratories. Bulk for an additional 400,000 units was on hand. The Bureau of Laboratories began immediate packaging of the bulk, permission having been granted by the U. S. Public Health Service to put this vaccine up in vials containing fifty doses each. The United States Army and Navy sent several hundred thousand units of vaccine gathered from all parts of the country. Since millions of units were needed to vaccinate the people in New York City, and this amount was not available, Mayor O'Dwyer called an emergency meeting at his office. Present at this meeting were representatives of the manufacturers of vaccine, members of the Health Department staff, and Dr. Thomas M. Rivers, Director of the Rockefeller Institute for Medical Research, and a member of the Board of Health. At the urgent request of the Mayor, the manufacturers went on a 24 hour schedule packaging their bulk vaccine and distributing all available supplies to this city. Retail pharmacists cooperated in distributing vaccine to private physicians. Vaccine supply stations were set up at a centrally located police precinct and at the Health Department.

Vaccination stations were set up in all police precincts, in addition to Health Department buildings and municipal hospitals and clinics. There was a total of 179 city installations being used for vaccination. Practically every hospital in the city set up a special clinic where vaccinations were given to all who applied, free of charge. The

vaccine was furnished by the Health Department and was administered by doctors on the hospital staff. Many community organizations set up local centers staffed by volunteer physicians and clerks. Labor and industry cooperated by establishing vaccination stations in factories, offices, and union headquarters. In some cases, their own physicians did the vaccinating; in others, it was performed by Health Department personnel. The stations maintained by the city remained open from 9 a.m. until 10 p.m., including Saturdays and Sundays. On April 26, those at the police precincts were discontinued, and on May 3 all other stations were closed.

In a period of less than a month more than 6,350,000 people were vaccinated in New York City, over 5,000,000 of them within the two week period following the appeal for universal vaccination made by the Mayor. Never before had so many people in one city been vaccinated in such a short time and on such short notice. Thanks are due to the press and radio for giving so generously of their space and time to bring necessary information to the public. Had it not been for them and for the intelligent cooperation of the public and the generosity of private physicians and volunteer workers, notably from the American Red Cross and the American Women's Voluntary Services and former Air Raid Warden groups, it would have been impossible to have achieved this remarkable record.

WHAT MIGHT HAVE HAPPENED

The introduction of virulent smallpox into a community, especially a large cosmopolitan city with rail, ship, and air connections with the rest of the nation and many parts of the world, could be a major catastrophe. For example, in 1945 in the Puget Sound area around Seattle, there were 65 cases of

CHART 2

ANNUAL TOTAL YEARLY RATES PER 100,000 POPULATION FOR FOUR URBAN AREAS

data for any differences that would render the populations incomparable. In regard to the latter, the differences in the small minority population groups pointed out above, would hardly explain the apparent large differences in rates noted between the northern and southern cities.

General Trends—

The validity of figures over a period of 10 or 15 years could be questioned because of the possibility that during such a short period of time not enough epidemic years for one or more cities would be included. Such a city might have experienced its epidemics in a slightly different cycle. Table 1 and Chart 2 showing the annual rates for 26 years reveal that, as a whole, all four

cities experienced the same epidemic cycles, 1925, 1927, 1930, 1934, 1939, and 1943. San Diego, however, experienced less sharp outbreaks (never a rate above 30), and had one extra outbreak in 1937. Occasionally it had two years in succession with rates above 10. Such endemic rates were not typical of the other cities. San Francisco and Oakland-Berkeley had maximal rates of approximately 37 and 40 respectively, and San Francisco had only one other year with a rate as high as 20, and frequently had rates of less than 1. San Diego and Los Angeles each had only one year with a rate below 1.

The general trends of both mortality and morbidity for the four areas for the 26 years (Table 1) have been similar to those for the United States in gen-

eral¹ and for Massachusetts.² Getting and Rubenstein have discussed these recently. Since the findings are similar for each study area, discussion will not be extended.

Seasonal Pattern—

Next, the monthly occurrence of reported infections has been examined. Cases, rates, and per cent distribution by month were tabulated for each year. Summaries of these for the 26 years are shown in Tables 3, 4, and 5 and in Charts 3 and 4. The seasonal distribution of the numbers and per cent of cases as shown in Table 3 and the mean monthly rates in Chart 3 give only the pattern of numbers, influenced predominantly by one or two epidemic years. For example, in the epidemic of 1934 in Los Angeles, a very unusual one in many respects, there were 534 cases (41.17 per cent of the total, or a rate of 39.56) in the month of June alone. This warps the peak of cases and mean of rates (Chart 3) to June, for the whole 26 years. Oakland-Berkeley, similarly, by the epidemic of 1934 has an apparent peak in June. Nevertheless, when

we examine Table 4 for the mean and median of the *per cent distribution by months* for the period of years, and Chart 4 for the median of the *monthly rates*, August appears to be the month most frequently showing the peak incidence of disease in both Los Angeles and San Diego. Examined in the same way, San Francisco shows a later peak (October), while Oakland-Berkeley, despite its geographical proximity to and a great daily intermingling of populations with San Francisco, shows a double peak by these three methods [highest in July, next highest in October, by mean and median of per cent distribution (Table 4) and highest in October with secondary peak in August by median of rates (Table 5 and Chart 4)].

When monthly mean maximum temperature peaks are compared to the median monthly rates for the southern and northern cities (Chart 4) it is observed that the peaks for infection rates are directly related to the times of highest monthly mean maximum temperatures—onset of largest number of cases occurring one month after the peak temperature.

Through the late winter and spring months neither the medians of monthly rates (Table 5) nor the medians of the per cent distribution by month (Table 4) can serve for comparison of three of the cities, for no cases occurred in many of the winter months during most years, resulting in medians of 0. It would thus appear at first, that persistence of infection throughout the late winter and spring was a peculiar characteristic of Los Angeles only, whose medians do appear in the tables. This, however, is probably only a factor of its greater population with increased opportunity for a few cases to be recognized during each winter month; for, on examining the *mean* per cent distribution (Table 4) it will be noted that both Oakland-Berkeley and San Francisco exceed Los

Angeles in December, as do San Diego and San Francisco in January and February, and as does Oakland in March.

At this time the question might be posed: Can we draw any conclusions from these data as to the effect of temperature on the epidemiology of polio-

CHART 4

MEAN MAXIMUM MONTHLY TEMPERATURE AND MEDIAN MONTHLY RATES PER 100,000 IN FOUR URBAN AREAS 1920 - 1945

myelitis? The answer is no! A review of the literature on the subject would be very time-consuming and offers no definite proof of any fact save that epidemics of poliomyelitis usually occur during the summer. However, one may

be permitted to speculate somewhat in the hope that further study will be stimulated to prove or to disprove any hypotheses which might be advanced. Possibly the relatively high, sustained temperatures (high summer minimums

or possibly mild winters) of an area like San Diego contribute to high endemicity, contribute to an environment conducive to the ready spread of the infection to a high proportion of the susceptibles annually, and thus tend to prevent large epidemics. Possibly the greater seasonal changes of Los Angeles and Berkeley produce physiological changes in the host and thus may render a higher proportion of the population susceptible to recognizable infection when exposed. Exposure of large numbers then occurs when there is occasionally a *chance correlation* of circumstances in the environment leading to *ready* spread of infection. Then, an epidemic occurs. Because of the usual wider swings of daily temperature or some related factor, these circumstances do not occur annually in Los Angeles or in Berkeley-Oakland. To carry comparisons further it might be suggested that the greater seasonal differences occurring in eastern cities produce greater physiological changes in the population. In these eastern cities more severe epidemics occur, with rates above 100 per 100,000, higher than have been recorded in any of these western cities. Possibly San Francisco has such remarkably low rates and freedom from all but mild epidemics because it is cool, or its population is sheltered from marked seasonal changes in temperature, or both. These are but a few of many suggestions that might be made. The author subscribes to none of them at the present time, but would welcome proof establishing or eliminating any of these hypotheses or others which have not been mentioned. Undoubtedly, the factors are complex, but it is quite possible that some important ones may be quite simple.

Age Distribution—

One of the most important and possibly most interesting phases to be considered is the question of difference in age distribution of cases between the

four communities. First, the trend in age distribution for each area will be examined. In order to make the data strictly comparable, all age-specific rates for each year have been adjusted to the population distribution of one of the cities.

On a first glance at the complete tabulation by five year age groups for each year by each city (tables not included) it became apparent that in the large epidemics in 1934 which affected principally Los Angeles, but also affected significantly the two northern cities, there was an unusually high percentage of adult cases. The peculiarity of this epidemic has been discussed previously in a number of other publications. In fact, it is questioned by many whether much of that which was reported as poliomyelitis in adults might not have been another disease. The influence of this strain of virus (if such is the explanation) can be noted in most areas of California through 1937; then the age distribution of other years appears to have become reestablished. Because of this unusual period, these four years, (1934–1937) are grouped together. The period before (1922–1933) has been divided into two series of 6 years each, and the last period of 8 years (1938–1945) has been treated as another group. Table 6 presents the grouped, age-adjusted rates and the per cent distribution of these by time periods for each of the four areas. Five age groups have been considered (0–4, 5–9, 10–14, 15–19 and 20+ years). The per cent distribution, only, is presented graphically in Chart 5.

In the age group 0–4 it will be noted that in all areas there has been a downward trend from 1922 to 1945. An irregularity however will be noted for the years 1934–1937 where the decrease was more marked, particularly in Los Angeles and in Oakland-Berkeley. San Francisco and San Diego were less affected. It may be noted also in Table

6 that the four cities maintain their same relative position for morbidity in this one age group as they did for total rates, San Diego, Los Angeles, Oakland-Berkeley, San Francisco. Data in Chart 5 cannot be compared in this manner since they represent per cent distribution of rates per age group. In the age groups 5-9 and 10-14 no significant change in the trend of the per cent

distribution of rates has occurred (Chart 5). The relative positions of rates for all cities for these periods of time show considerable change, but the most striking change is again that due to the epidemic of 1934 in Los Angeles.

In the 15-19 and 20+ age groups a general increase in trend is noted. This is greatest in the older age group (Chart 5). The unusual 1934 outbreak shows

San Francisco	24.9	10.3	38.2	16.2	21.6	10.3	8.6	3.0	1.5	0.3

its effect principally on the group over 20 years, again particularly in Los Angeles. Apparently an opposite trend occurred in San Francisco. The great irregularities in the 15-19 group for San Francisco are partially reflected in this latter irregularity. In these last two age groups the relative standing of the rates is again affected markedly by epidemic years when examined for the 1934-1937 year group (Table 6). It will also be noted that in the period 1938-1945 San Diego's rate for the 15-19 year age group is completely out of

line, lower even than San Francisco's. The reasons for this obvious inaccuracy have been explained previously.

Since apparently, there have been relatively similar trends in these four areas throughout the 26 year period, it is probably safe to examine the means and particularly the medians of the age-adjusted rates for the total span of years. These are presented in Table 7. In Table 8 the mean and median per cent of cases by age groups is presented. The cases have not been adjusted for age differences in population, but, as

above grew also on the gentian violet plates as a mucoid translucent colony. These colonies were counted, picked, and set up directly in types 23 and 32 pneumococcal typing sera for identification.

Ward Technique of Handling Patients

—In so far as possible, an aseptic technique was followed when caring for the infants. Gowns, hung in the open ward at the entrance of each cubicle, were worn by the nurses and attendants when the infants were fed, dressed, changed, and had their beds made. Masks were also worn when very young infants were handled. Gowns were changed and hands washed thoroughly before and after caring for each patient. Attendants with upper respiratory infections were isolated during the acute phases of illness or required to wear masks while on the wards. In the case of emergencies and during ward rounds these techniques were not always carried out.

Patients—Infants from 1 day to 2 years of age were admitted to the wards with a wide variety of medical and surgical illnesses. There were 130 patients in the control and 140 in the test wards who stayed a sufficient length of time (5 days) to be included in the study. They were admitted, as far as possible, alternately to the test and control wards. In a few instances, some cases were shifted purposely from one ward to another. As shown in Table 1, the mean age of the patients and the time spent in the hospital were comparable on the two wards.

Approximately half of the patients had respiratory tract or skin infections at the time of admission. The results of the admission nasopharyngeal cultures are shown in Table 2. There were only 3 cases admitted to the wards with cultures positive for hemolytic streptococci. Actually, one of the cases on the test ward was a transfer from the control ward with the positive culture. The majority of the infants showed positive cultures for one or more types

TABLE 1

Comparison of Experience of Patients with Respect to Age and Time Spent in Hospital

Beta Hemolytic Streptococci (group A, types 2, 33)	1	2
Gram-negative Bacillus	2	1
Pneumococci (different strains)	67	96
Per cent most frequent		
*Pneumococcal Types (6, 14, 19, 23)	55	44
Per cent (24) additional types	45	56

of pneumococci. The most prevalent types, which made up approximately 50 per cent of the strains isolated, were 6, 14, 19, and 23. Twenty-four additional pneumococcal types were isolated (Table 2).

Sulfonamide and Antibiotic Therapy

—Soon after the study began it became evident that consideration would have to be given to the use of sulfonamides and penicillin on the wards. These drugs, although of great benefit to the patient because of their antibacterial activity, constituted a factor which must be considered in the analysis of the findings if the experience of the two wards was to be compared. Accordingly, the experience of the patients in each of the two wards was divided into: (a) hospital days with no chemotherapy, and (b) hospital days with chemo-

constant but serious danger does not make newspaper headlines! For example, in recent years, many parents have hesitated considerably to take their children to Los Angeles during the summer because of its local reputation for frequent poliomyelitis "epidemics." Many have repeatedly sought advice of the author and others in various health departments in regard to the dangers of a visit to this southern city or to its neighboring communities. To my knowledge, such a question has never been raised regarding the "epidemic-free" city of San Diego which, while it maintains a high "endemic" rate, does not make spectacular headlines.

Paul⁵ recently has reported the mortality rates for poliomyelitis in Japan, 1923 to 1943, and noted that although epidemics have been rare, the average overall mortality rate for this period differs little from that observed in the same period in the United States. Reported cases in Japan occur relatively more frequently in the 0-4 year age group than those reported in recent years in the United States. Since the general level of physician training and probably the accuracy of diagnosis in Japan may be considered well below that in the United States, the rates reported are probably lower than they should be for real accuracy. It should be noted that the extremely low rates quoted from many tropical countries may in no way accurately reflect the incidence of poliomyelitis, but rather indicate the low standard of diagnosis and reporting.

One other interesting observation may be made from Chart 6 of the median per cent of cases by age groups. Berkeley has a higher per cent of cases in the age group 15-19 than do the other cities. It seems probable that the enormous population of the University of California results in this peculiar age distribution of cases. On the basis of age-adjusted rates it is not out of line.

The most marked differences in the four urban areas of California appear in the age group 5-9. San Francisco (Table 7) although it still holds lowest place in the median of the rates for this age group (about one-half of that of San Diego) and ties for the lowest position in the mean of the rates, has a higher proportion of its total number of cases in this age group, on the basis of either mean or median (Chart 6, Table 8), than do any of the other cities. In fact, these four cities by both means and medians of the relative distribution of cases by age group, assume the inverse relationship of the order of total rates, in the 0-4 year age group, or per cent of cases in the 0-4 year age group. It would thus appear that the trend of difference in per cent of cases between the 0-4 and 5-9 year age groups might in some way be a measure of, or at least be related to, the total incidence of the disease in a community, or of the factors disposing to the disease. This conjecture should receive further study in many communities before it may be accepted or rejected.

Differences in the medians of the age-adjusted rates for the remaining, three older age groups (Table 7), quite consistently hold the order of incidence maintained generally by the four cities. In other words, in any one year (on the basis of a median) at any age, one is apparently less likely to develop infantile paralysis in San Francisco than in any of the other areas studied, and is most likely to develop it in San Diego. The one apparent exception to the latter is the 15-19 age group which we have pointed out shows rates which are obviously too low. On the basis of means *reflecting a 26 year period of exposure in any one age group*, one is still safest in San Francisco except during the years from 10 to 14 when Berkeley or Oakland might be a safer place of residence. However, one's greatest danger at any age for prolonged residence would

possibly be in Los Angeles. Here, though infection during non-epidemic years is less likely to occur than in San Diego, chances of infection are greatly increased during an epidemic year. This short digression into impractical and possibly ludicrous interpretation has for its purpose simply to show the significance of the means and medians used in this phase of the study. Of course, the writer prefers to keep his family in San Francisco, but should he be forced to choose between San Diego and Los Angeles, other factors would have to be considered in making the decision.

Before closing, a word to anticipate the questions of the statisticians may be in order. Where are the standard deviations for rates and means? Are the differences shown and discussed statistically significant? There has been careful avoidance of any claim up to this point that any of the differences are significant, and the discussion has been based on apparent differences only. However, the consistency of the findings through the breakdowns, by age

groups and by periods of years, with rather obvious explanations available for the few discrepancies encountered, lends considerable weight to the probable significance of at least the more marked differences noted.

ACKNOWLEDGMENT—Much of the original data were collected as a student project from the files of the California State Department of Public Health, under the supervision of Miss Ida May Stevens, of the Division of Communicable Diseases, by Mrs. Toshiko S. Yoshida. The author was assisted in making the tabulations, and calculations by Mrs. Susa H. Condliffe and Mrs. Fern E. French.

Antibiotic Symposium

The Medical Sciences Section of the American Association for the Advancement of Science will present a symposium on Antibiotics on December 29 and 30 in connection with the Annual

Meeting of that Association in Chicago, December 26-31. This symposium will be given in four half-day sessions at the Hotel Sherman, beginning at 9:00 A.M., Monday, December 29.

Methods of Removing Fluorides from Water*

F. J. MAIER, B.S.M.E., B.S.C.E., F.A.P.H.A.

*Sanitary Engineer, Dental Public Health Section, States Relations Division,
U. S. Public Health Service, Washington, D. C.*

INTRODUCTION

FLUORIDES in drinking water can be beneficial or detrimental depending on their concentration. Recent epidemiological studies have indicated that there is an inverse relationship between fluorides and dental caries experience.^{19, 22, 24} The promise which this relationship holds for mass control of dental decay, however, hinges on the fact that an optimal caries prophylactic effect of the fluoride is obtained within the range of 1.0 to 1.5 parts per million (p.p.m.). Greater concentrations are associated with a hypoplasia of the teeth known as mottled enamel or dental fluorosis. It is the purpose of this presentation to examine current methods for removing excessive fluorides from communal water supplies in order to prevent the occurrence of dental fluorosis. Inasmuch as present evidence suggests that the removal process should not effect a fluoride reduction below 1.0 p.p.m. in order that the beneficial effect of caries inhibition may be retained, this discussion will be concerned with the defluorination of water to the optimal limit.

Near the beginning of the 20th century mottled enamel had been noted and described.²⁵ Despite the intensive researches of several investigators, however, it was not until 1931 that its

cause was correctly determined and announced, almost simultaneously, by Churchill,¹⁴ Smith,⁴⁹ and Velu.⁵⁹ Since the discovery that fluorides were the cause of mottled enamel in the permanent teeth of children, the problem of removing excess fluorides from drinking water has been studied widely.

In 1935, Dean and Elvove^{16-18, 21} began to publish the results of their epidemiological studies relating to minimal concentrations of fluorides sufficient to produce mottling. They found that a fluoride concentration of 1.0 p.p.m. or less in a communal water supply produced no significant mottling of the teeth of children who had been using this water continuously. With higher concentrations, mottling was progressively more severe and above 6.0 p.p.m. almost all children were afflicted. In addition to mottling at this high concentration, gross calcification defects and attrition of the enamel were observed. For this reason, the dental defects caused by fluorides in drinking water are better termed dental fluorosis.

After the cause of dental fluorosis was discovered, several methods were devised for removing excessive fluorides from water. Nevertheless, at the present time (excepting some lime softening plants) only one community is known to be utilizing equipment specifically installed to reduce the fluoride content of its water supply. The lack of application of preventive measures maintains despite the undesirable disfigurement

* Presented before the Dental Health Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 7, 1947.

associated with fluorosis, the increased costs of dental care and the fact that the number of persons using water containing excessive fluorides (over 1.5 p.p.m.) exceeds 1,000,000 persons in over 500 communities.⁵⁸ This situation may be attributed to a combination of several factors, most important of which are the high capital and predicted operating costs of the removal processes and the complexity of the operating procedures.

It is impossible or impracticable in many communities to change the source of supply to one having a satisfactory fluoride concentration. Dental studies have been made in three communities, however, which previously used water high in fluorides and then changed to other sources having little or no fluorides.²³ The change resulted in no additional cases of fluorosis.^{20, 40} No community has as yet removed excessive fluorides from its water and subsequently measured the results in terms of a reduction in the incidence of fluorosis.

FLUORIDE REMOVAL METHODS

The methods utilizing the fluoride exchange properties of the apatites, such as those involving the use of the constituents of bone, the ion exchange principle, and those depending on the sorptive properties of aluminum compounds, appear to show the most promise for removing excess fluorides from water. In addition, where the fluoride concentration is not very high (less than 4.0 p.p.m.), processes involving the concurrent removal of magnesium are indicated, if hardness reduction is also contemplated.

CALCIUM PHOSPHATES

The use of bone for removing fluorides is based on the long known affinity of bone for fluorides. Probably the most plausible theory of the chemistry of this affinity may be explained on the

basis of the anion exchange properties of apatites. The carbonate radical in the apatite comprising bone, $n\text{Ca}_3(\text{PO}_4)_2 \cdot \text{CaCO}_3$ is replaced by the fluorides in the water, forming an insoluble fluorapatite.⁵⁰ In the regeneration of the material with sodium hydroxide the fluorapatite probably becomes an hydroxy-apatite and the fluorides are removed in the form of soluble sodium fluoride. The hydroxy-apatite subsequently becomes available as an exchange material by the replacement of its hydroxy radical with fluoride.

One method of preparing bone for use as a fluoride removing agent⁵¹ involves boiling to remove the fat and most of the protein. It is then crushed and boiled in a solution of sodium hydroxide. The caustic is removed by thorough washing and finally is neutralized with hydrochloric acid. The material is again washed and then dried and graded for fineness. Home filters in which the prepared bone is utilized are available but there have been some objections to the taste of the treated water. Based on the expense of renewing the bone media in home filters, the cost of using this method in a municipal plant would be exorbitant (approximately \$25,000 per m.g.).^{*} It is reported⁵⁰ that the material can be regenerated successfully by a sodium hydroxide and acid wash method, similar to that used in its preparation. Data are not available on the removal capacity of the bone after it has been subjected to numerous regenerative cycles when used with waters naturally high in fluorides and other mineral contaminants.

A similar process utilizes virgin bone black (animal charcoal) which is essentially tricalcium phosphate and carbon.¹³

* All chemical cost estimates, except where otherwise noted, are based on a fluoride ion (F^-) reduction from 6.0 p.p.m. to 1.0 p.p.m. at current (1947) chemical quotations.

In its limited use in household filter units, the material is discarded when its exchange capacity is exhausted. In a municipal installation, the cost of this procedure would be excessive (\$5,000 per m.g.). Regeneration of the material has been effected with solutions of trisodium phosphate and mono-sodium phosphate but the exchange capacity of the bed is reduced by 12 per cent after the first regeneration.

The principal chemical constituent of bone, tricalcium phosphate, can be prepared from phosphoric acid and milk of lime. The product consists essentially of tricalcium phosphate and its hydroxyapatite. Because it forms a gelatinous floc in water, fluoride removal is probably accomplished by adsorption together with the formation of a fluorapatite.^{1, 26, 28}

A porous, granular type of tricalcium phosphate has been developed for use in contact filters.³ When the fluoride removal capacity of the bed is exhausted, the material can be regenerated with a 1 per cent sodium hydroxide solution. About one pound of caustic soda is required for each cu. ft. of tricalcium phosphate.³⁰ The causticity of the bed is then neutralized by thorough washing with water and with a carbon dioxide solution.⁷ The use of carbon dioxide for this purpose, rather than hydrochloric acid as originally proposed, greatly increases the life of the bed and considerably reduces attrition losses.⁸ The rated removal capacity of tricalcium phosphate is 300 grains of fluoride per cu. ft. but this capacity decreases about 3 per cent for each 100 p.p.m. sulfates present in the water. The iron content of the water must be reduced to 0.10 p.p.m. in order to prevent clogging of the filter. A water treatment plant using this material has been operated since 1937.⁶⁰ The fluoride content of the raw water varied from 2.0 to 14.0 p.p.m. and averaged about 8.3 p.p.m. The effluent contained an average of

0.6 p.p.m. The chemical costs for the fluoride removal process at this plant totaled about \$130 per m.g. in 1944.

Tricalcium phosphate can also be formed from ortho-phosphoric acid and lime within the mixing chamber of the conventional type of treatment plant (mixing flocculation, settling and filtration).^{37, 38} The tricalcium phosphate thus formed must be removed continuously from the water and discarded. The chemical cost of this process amounts to approximately \$245 per m.g. A similar material for fluoride removal, trimagnesium phosphate, has been suggested,² but is reported to be less efficient and more expensive than tricalcium phosphate.

ADSORPTION WITH ALUMINUM COMPOUNDS

In addition to the constituents of bone for fluoride removals, a large number of other materials have been tested. These materials include aluminum sulfate, sodium aluminate, zeolites, bauxite, silica gel, sodium silicate, ferric fluoride, lime,¹¹ and various adsorbent clays and earths.⁴¹ With the exception of aluminum sulfate, all of these materials have been found to be impracticable probably because of the very low initial concentration of the fluoride ion, and in some instances because an undesirable proportion of the reagent remains in the water due to the excessive amounts of chemicals required. Aluminum sulfate and other aluminum salts have been used in combination with insoluble compounds in contact beds or as constituents of floc which is subsequently removed by settling and filtration. The fluorides might be removed by the formation of an aluminum fluoride complex or by adsorption on the floc. In addition to the fluoride removal characteristics of the aluminum compounds, they are relatively inexpensive, easy to use, and can be combined advantageously with aids to coagulation

such as clays and activated silica. The results reported on the effectiveness of aluminum hydroxide floc formed from aluminum sulphate and a source of alkalinity vary considerably. The variations can be attributed to such factors as the following: different raw waters with varying induced fluoride concentrations were used; the speed of adding the reagent and methods of mixing were different¹²; the times of contact varied; the pH was not the same; and, not all of the effluents were filtered. In general, however, 4.0 p.p.m. fluorides are removed from water when hydrous aluminum sulfate is used in concentrations of 335 p.p.m.,¹¹ 430 p.p.m.,³⁴ or 513 p.p.m.⁴⁷ According to one investigator, it required 891 p.p.m. aluminum sulfate to reduce fluorides from 6.0 to 1.0 p.p.m.⁴⁷ while according to another^{34, 35} 860 p.p.m. were required to obtain a reduction from 8.5 to 1.0 p.p.m. In order to obtain maximum fluoride reductions, optimum hydrogen ion concentration is necessary but the pH can be controlled in treatment plants by adjusting the chemical feeders.

Fluoride removal experiments in which aluminum sulfate and coagulation aids (clays and activated silica) were used together with alkalin solutions for pH control, were conducted recently in the Industrial Hygiene Laboratories at the National Institute of Health and in pilot plants at Great Falls, Md. (Potomac River raw water), and at Cincinnati, Ohio (Cincinnati City water).³⁹ Fluoride concentrations¹⁰ were determined by using the Scott modification⁴⁸ of the Sanchis procedure⁴⁰ and the Lamar adaptation³⁰ with a spectrophotometer. The results with the conventional type of plant at Great Falls (mixing, flocculation, settling, and filtration) indicated that fluorides can be reduced in two steps (6.0 to 3.5 p.p.m. and from 3.5 to 1.0 p.p.m.) using in each step 100 p.p.m. aluminum sulfate, 100 p.p.m. clay, and

about 25 p.p.m. lime. In an improvised experimental sludge-blanket type plant (precipitator) in Cincinnati approximately 25 per cent more fluorides were removed using the same chemical dosages as at Great Falls. When activated silica (Baylis Sol) was used in conjunction with alum, clay, and soda ash, a further reduction in fluorides was noted.^{4, 5, 6, 32, 33} Based on the quantities of chemicals used in the conventional pilot plant the cost is estimated to be about \$35 per m.g. The process is not as efficient with highly mineralized ground water in which excessive fluorides are naturally present. The reason for decreased efficiency under the latter conditions is not known.

Another method utilizing aluminum salts involves contact beds of insoluble material impregnated with aluminum compounds. The earliest report⁴³ suggested soaking filter beds of sand or diatomaceous earth with the precipitated hydroxide of aluminum sulfate and an alkali. The data available on the fluoride removal efficiencies of this method are not sufficient to serve as a basis for estimating costs.

A similar method involves pickling base exchange materials⁵⁴ (natural or synthetic zeolites) or naturally adsorptive materials⁵⁵ in aluminum salt solutions. Although these pickling solutions are highly concentrated, five hours of contact are required before the exchange material has been converted to an anion exchange compound. The aluminum ion is presumed to have entered into the chemical structure of the material and reversed its exchange mechanism. When the bed is exhausted, it can be regenerated with soluble aluminum salts. This method is the least efficient of those in which aluminum soaking is involved.⁴⁴

Another method involving aluminum salts and utilizing contact beds is based on the formation of insoluble compounds in the presence of excess aluminum ions. The insoluble compounds thus formed

are alleged to possess a fluoride removal capacity several times that of materials of the base exchange group. The superior performance is attributed to the much higher concentration of aluminum salts in solution and to the concomitant increase in adsorbed uncombined aluminum ions.⁵⁶ The insoluble compounds can be made from either sodium silicate, barium chloride, sodium phosphate, ferrous sulfate or titanium chloride in the presence of excess aluminum salts. The precipitates formed are washed, dried and graded. Regeneration is accomplished by washing the bed with solutions of either aluminum salts or dilute mineral acids or alkalis. No data are available on the fluoride-removing capacity of this method or of its efficiency after repeated regenerations. Until other commercial uses can be found for the insoluble materials used in this method, their cost for fluoride removal will probably be too high for use in municipal installations.

Dehydrated aluminum oxide (calcined alumina)¹⁵ or partially hydrated alumina³¹ have been suggested for use in contact beds. The calcined alumina (activated alumina) has been tried in field tests^{29, 52} and rated as fairly good with respect to fluoride removal efficiency. When the bed becomes exhausted the fluorides are removed by washing with a dilute caustic solution and neutralized with a dilute acid solution. Chemicals for regenerating the materials used in this method amount to \$275 per m.g. Because tricalcium phosphates have a better removal capacity and a lower regeneration cost than activated alumina, the latter is no longer advocated for municipal treatment plant use.

Other hydrated metallic oxides have also been suggested for removing fluorides. These include ferric oxide, chromium borate, mixed oxides of iron and manganese, bauxite and bog iron ore. All can be regenerated to varying

degrees but ferric oxide is probably the most efficient.³¹ Using caustic soda and carbon dioxide solutions for regeneration, chemicals cost approximately \$250 per m.g.

ION EXCHANGE PROCESSES

While the compounds which are subjected to aluminum solution soaking probably involve a combination of ion exchange and adsorption principles in fluoride removal, several additional products are claimed to involve predominately ion exchange processes. One of these is made from barium or ferric chloride and silicic acid with the formation of a complex metal chloride silicate. It is claimed⁵³ that the fluorides are removed from water when in contact with this material by exchange with the chloride ions. Regeneration of the materials has not been advocated and no data are available on capacities or costs. Another compound is obtained from asphaltic materials heat treated with an alkali.⁵⁷ Fluorides are presumed to be removed by anion exchange with the hydroxide. Regeneration is accomplished with an alkali but capacities and costs have not been determined.

Recently an organic resinous anion exchange material made from various diaminobenzenes or phenols and formaldehyde has been announced.⁴⁵ It is alleged that this material is somewhat selective for fluorides, removing in addition only iron, copper or other metals yielding insoluble hydroxides.⁴⁴ The material is first conditioned with a 4 per cent soda ash solution, neutralized with a dilute acid wash (500 p.p.m. hydrochloric acid) and then soaked with a 4 per cent solution of aluminum sulfate. The exchange capacity is based on 1,240 grains of fluorides per cu. ft. Chemical costs for regeneration amount to about \$90 per m.g. Further tests on this material to determine the effect of higher concentrations of radicals commonly found in ground waters and the

possibility of utilizing other regenerating chemicals are now in progress.

OTHER METHODS

The use of lime for fluoride reduction was known soon after the cause of fluorosis was discovered.¹¹ In a study of the results of lime softening plants in Ohio,⁴⁷ it was determined that fluoride reduction with lime was actually a function of the amount of magnesium removed. When waters were fluorinated with sodium fluoride and treated with magnesia, it was demonstrated that the magnesia first becomes partially hydrated, then magnesium fluoride and sodium hydroxide are formed by metathesis and finally the magnesium fluoride is attached to the magnesia, forming perhaps an oxyfluoride.⁶¹ The results of samples examined from the softening plants indicated that the quantity of fluorides removed approximately equaled the product of 7 per cent of the initial fluoride and the square root of the amount of magnesium removed. Between 45 and 65 p.p.m. magnesium must be removed to reduce the fluoride one p.p.m. Theoretically, if a residual fluoride of 1.0 p.p.m. is desired, 100 p.p.m. magnesium must be removed if the initial fluoride content is 3.3 p.p.m. A magnesium concentration of this magnitude is rare in most high fluoride waters. Consequently employment of this method would involve the addition of magnesium preferably in the form of dolomitic lime, calcined magnesite or activated magnesia.^{9, 26, 27} For average waters containing 6.0 p.p.m. fluoride and relatively high magnesium (20 p.p.m.), about eight tons of chemicals would be required per m.g. (carbon dioxide for pre- and post-carbonation, dolomitic lime and aluminum sulfate). The chemical costs would aggregate \$120 per m.g. Despite this relatively high cost and the large quantities of chemicals required (involving principally

sludge disposal problems), this method appears to be particularly applicable in the treatment of hard waters which require softening and which contain less than 4.0 p.p.m. fluorides. A refinement of this process provides a source of carbon dioxide for pre-carbonation,⁹ which is necessary to convert the magnesia to magnesium carbonate. The carbon dioxide is produced from conversion of bicarbonates by passing the water through hydrogen exchange materials.

Other chemicals and processes have been reported, many of which proved to be ineffective or impracticable. Activated carbon is quite efficient and its use is based on sound chemical principles.⁴² Almost complete fluoride removal is possible, however, only when the pH of the raw water is less than 3.0. No fluoride is removed at a pH of 8.0 or higher. Regeneration is possible with weak alkaline and acid solutions although no reports have been made as to the removal capacity of the carbon after repeated regenerations.

About one-half the fluorides originally present in water are removed using dosages of approximately 2,000 p.p.m. of either Wyoming bentonites, Fuller's earths, celite, or silica gel. To obtain this removal, however, the pH of the raw water is reduced to 2.5. In no case is any fluoride removed when the pH of the water is 8.3.⁴¹ Because of the inefficiency of these materials and their pH requirements their use is impracticable for fluoride removals.

SUMMARY AND CONCLUSIONS

More than a million persons in over 500 communities in the United States are now using public water supplies containing in excess of 1.5 p.p.m. fluorides. The disfiguring dental condition which is caused by the use of such waters for drinking purposes can be prevented in future populations of these communities by removing the excess fluo-

rides from the communal water supplies.

Most of the removal processes now available appear to be either too expensive to operate or too complicated for routine application by the average small water treatment plant operator. An urgent need is the development of a process comparable to the lime-soda ash softening process in operating costs and simplicity.

The problem of choosing the most practical method of defluorination for a particular supply is difficult, because of the almost complete absence of operational data. The choice of method for the accomplishment of a similar purpose as in other treatment processes, depends, by and large, on the rate of water consumption and on the characteristics of the raw water. For large municipal plants which treat waters requiring a reduction in hardness, it is advisable, in general, to reduce the fluorides as much as possible by the lime softening process. In some cases it would be economical to balance the costs of pre-carbonation and sludge disposal against the addition of a limited quantity of magnesium compounds. Excess fluorides remaining after this process could be removed in gravity contact filters or by an aluminum-clay floc, with subsequent separation of the floc from the water.

In small plants where softening is not desired, pressure contact filters appear to be more economical. Where the water is hard, lime softening is indicated up to a raw water fluoride content of about 4.0 p.p.m. If the fluoride exceeds this figure in hard waters, the remaining fluorides can be removed by contact filters.

The tricalcium phosphates and the resinous ion exchangers, when used in contact filters, appear to have the highest exchange capacities for fluorides. Furthermore, the chemical cost for regeneration of these materials is relatively economical.

It is evident from this examination of fluoride removal methods that our current knowledge of the chemical processes involved is very limited and that additional fundamental research in this field is needed. Further, the practical usefulness of the available methods and those now undeveloped must be tested on a pilot plant scale, and their relative worth under varying conditions must be determined. Until this information is available, endemic fluorosis will continue to be a dental hazard to a large population in many communities in this country.

Problem Drinking—A Public Health and Municipal Responsibility*

LYMAN C. DURYEA, M.D., M.P.H., F.A.P.H.A.

Medical Director, The Research Council on Problems of Alcohol, New York, N. Y.

INTRODUCTION

*Nature of a public health problem—*What constitutes a public health problem? Surgeon General Thomas Parran some years ago formulated the following definition: "Whenever a disease is so widespread in a population," he said, "so serious in its effects, so costly in its treatment that the individual cannot deal with it himself, it becomes a public health problem." Problem drinking fits every facet of this definition.

Alcoholism, or problem drinking as we prefer to call it, is a matter of public concern "whose health features," according to Dr. Lawrence Kolb, former Assistant Surgeon General, U. S. Public Health Service, "have been obscured by social and legal factors."

*Problem drinkers as a public health problem—*Regardless of our personal convictions regarding the use of alcoholic beverages and of our reactions to the manifestations of excessive drinking—drunkenness (and regardless of the causative factors underlying the drinking compulsion)—the fact remains that when one once becomes an uncontrolled drinker he is a sick person.

Acute alcoholic intoxication is a medical condition requiring medical care just as is intoxication from barbiturates voluntarily taken for insomnia or tension. Yet we accept for treatment in

our hospitals barbiturate intoxicants, but refuse hospital treatment to the alcoholic who is acutely ill or in a stage of exacerbation of a chronic illness. Dr. E. M. Bluestone, Director, Montefiore Hospital, New York, in the foreword to the American Hospital Association report on *Institutional Facilities for the Treatment of Alcoholism* said, "The medical profession has been so absorbed in the pressing problems of other diseases that they have played into the hands of a sanctimonious group in our midst, who would have such patients stew in their own juice, and who have no sympathy for a scientific medical approach to this peculiarly baffling malady," and I might add even as they had for years regarding victims of the mental and venereal diseases.

A tour through the "Skid Rows" of our cities, which include the Bowery in New York City, will remind one of the Russia of a century ago described by Tolstoy, a time when there were few asylums or hospitals for the mentally ill and nearly everyone had a neighbor with some mental disorder. These people were part of the landscape as our inebriates on the skid rows and the boweries of the cities of our country are today. At the present time, in this country, through the efforts of the medical profession and as a result of the demand of an enlightened public, most of the mentally ill have been removed from the streets and provided

* Address delivered at the annual Conference of the Health Officers and Public Health Nurses Association, Saratoga, N. Y., July 30, 1947.

with facilities and treatments undreamed of but a few years ago. This is not true of the alcoholic.

How many of us are there who do not know some really worth while person who occasionally or frequently drinks to excess—with resultant familial and economic problems? How many of us have not thought of chronic drinkers at times as annoying drunks or stumble-bums? But what was our attitude toward venereal disease not so long ago? The alcoholic, the problem drinker, remains the only diagnostic entity for whom we provide few or no facilities for treatment. This is the only condition requiring medical attention whose victims are treated as criminals and remanded to jails through court action. As Dr. Ray Lyman Wilbur, Chancellor of Stanford University, stated in a recent communication to me, "Our whole set-up for rehabilitation of the drunkard is imperfect and often vicious. From the time he is picked up by the patrol, passed from the jail to the police judge, and from there on, there is constant failure to meet the situation. We must go back and get some fresh starts in our thinking. Our newspapers, the public in general, our courts, our doctors and social workers, all seem to me to have the wrong approach to this question. Fundamentally, the chronic drinker is a problem for the doctor. It is evident that we shall need to give special training and provide special facilities if we are to accept the use of alcohol and its public distribution as part of our so-called civilization."

The problem drinker is a sick individual, whether he is suffering from some physiological deficiency, whether he was emotionally sick previous to his excessive drinking, or whether he is socially maladjusted. He is as much sick because of the causes of his drinking as because of the end-products of it.

Problem drinking is not a specific disease as is malaria. Rather it is a con-

dition presenting a multiplicity of symptoms, the most predominant of which is excessive drinking. So far there is no accurate scientific analytical definition of what problem drinking actually is. It is a problem on which there is more misinformation than information. We see a symptom of the disease, drunkenness. We recognize a drunkard but cannot define in scientific or legal terms the absolute character of his condition, nor what causes him to be a drunkard, nor why he cannot stop drinking once he has started, nor what changes take place in this individual which result in an uncontrollable and insatiable desire for more alcohol.

Chronic drinking is a matter of concern to us all, not merely because of its unknown elements, its neglect in social terms, its waste, but also because of its magnitude. In many communities it exceeds tuberculosis. It is a public health problem because of the number of people involved, the inability of the individual or his family to cope with it, and finally because of its effect on our society.

Extent of the problem—It has been estimated that 57 per cent of the male population and 29 per cent of the female population between the ages of 15 and 60 years use alcoholic beverages. This is 44 per cent of the entire population in this age group. The total estimated number of excessive drinkers is 3,750,000, or approximately 6 per cent of the drinking population. Of these, 750,000 may be considered problem drinkers. The prevalence of intemperate drinking is estimated to be between 2.5 per cent and 3 per cent of the adult male population, and there are estimated to be 6 times as many men as women among heavy drinkers. It may be concluded conservatively from these figures that problem drinking is of considerable magnitude.

The urban-rural breakdown has been recently estimated by Dr. E. M. Jellinek

of Yale University. His estimates for chronic alcoholism are as follows:

In cities with a population of 100,000 or over.....	972 per 100,000
In cities with a population of 10,000 to 100,000.....	727 per 100,000
In cities with a population of 2,500 to 10,000.....	743 per 100,000
Rural (less than 2,500).....	474 per 100,000

New York State ranks third throughout the country with an estimated chronic alcoholic rate of 1,034 per 100,000 of population. This is an increase of 34.3 per cent over the rate of 770 per 100,000 in 1930 when New York ranked eighth. In Albany, N. Y., for example, in 1940, the latest year for which rates are available, the rate was 725 per 100,000.

These figures may be considered as reliable estimates with the possibility of variations, plus or minus. The sources of these estimates and the indices by which they are arrived at cannot be regarded as accurate statistical data. Many of us in this field, however, regard the estimates as representing the "least possible number."

PRESENT-DAY HANDLING OF THE PROBLEM

Hospital facilities—In the foreword to the American Hospital Association's report *Institutional Facilities for the Treatment of Alcoholism*, Dr. E. M. Bluestone said, "The false spirit of humor which unhappily surrounds the alcoholic patient and endows him with a certain grotesqueness, and the stigma which is fastened upon him to his lasting disadvantage, combine to withhold, from the sick man that he is, the medical care that is his right and privilege. Most of our hospitals have thus far failed to dignify alcohol addiction as a disease worthy of study and intensive care. Every kind of patient has been provided for, in one type of hospital or another, including the leper whose traditional position as an outcast has not

deflected us from planning for his care. The problem (of alcoholism) demands the aid of the best medical brains and the use of the facilities of every hospital. Doctors and hospitals have, however, maintained a hands-off policy toward the alcoholic patient which is practically universal. Yet every forward move in medical and hospital progress points invitingly to the solution of this problem. There must be a scientific solution to this problem, without resort to extreme measures, and our general hospitals are peculiarly situated to take the lead because they enjoy the best in medical talent, investigative facilities, and educational arrangements."

More recently, the New York Academy of Medicine, under a grant from the Research Council on Problems of Alcohol, found that, "while it is true the majority of the reporting physicians do not treat alcoholism, this does not reflect a lack of interest in this problem on the part of the medical profession but rather a feeling of futility and a realization that specialized knowledge is required to deal effectively with the various phases of it." The Academy of Medicine also found that, "in New York City neither the voluntary hospitals, except one, nor the proprietary institutions of various kinds, except one, have made provision for the treatment of alcoholic patients. The institutions which take alcoholics treat them only during the acute stage.

"Since the number of alcoholics treated in New York in voluntary hospitals and proprietary institutions, as well as in private practice, is apparently small, it remains an enigma as to where and by whom the purportedly large contingent of alcohol addicts is being treated. The conclusion that they receive little attention seems justified." Meager as is the *municipal* hospital care of problem drinkers, "New York is one of the few cities in the United States

in which the treatment of alcoholism is regarded as a hospital and not primarily a police problem." This is the view of the officials of the City of New York.

In general, however, the patient suffering from chronic drinking is too often consigned to the police or, still worse, left to his own devices without constructive aid from doctors or hospitals unless he is a man of wealth, in which case he can obtain care of a palliative sort. If he is poor he is doubly cursed. In his inability to cope with his problem himself he gets kicked around not only by society but by those of us who in our hearts should know better. We must not lull ourselves into believing we can dispose of the problem by pleading that we have other work to do for those whom we consider more deserving. Who is to select the most deserving in our midst?

The jail—Despite the emerging concept that problem drinking is a symptom of complex, little understood, causative factors and that it is a medical problem requiring medical care, intoxication and problem drinking generally are legally considered practically as criminal offenses. Problem drinkers, in acute exacerbation, and episodic or occasional acute alcoholics, usually come before the courts. In most of our local jails problem drinkers and episodic drunks constitute 50–60 per cent of their population. They have become in effect chronic disease hospitals, for which they are neither staffed, equipped, nor originally constituted.

Although increasingly more and more jurists and penologists are becoming aware of the medical nature and needs of problem drinkers, they are at a loss as to how to handle the problem. One of them recently remarked to me, "I am aghast at the seriousness of this problem. I don't want to send these men to jail, where they will receive no treatment and from which they will emerge to repeat the cycle of intoxica-

tion and commitment over and over with harm to themselves, their families, and the community. But what can I do with them? There is needed constructive, municipal planning to provide for adequate case finding, treatment, prevention, and rehabilitation."

These might have been the words of a health officer instead of a lawyer. That such planning is little in evidence at this time needs no further restatement, nor that the need for it is great; yet many problem drinkers could be saved, if in the early stages of their chronic drinking they were handled like sick people instead of being treated like criminals or allowed to shift for themselves. They are serious problems for the police, the courts, and the welfare agencies; serious problems, in the main, poorly handled. They are an economic deadweight on society. Yet, on the basis of economics alone, they are worth helping. Take one group alone, Alcoholics Anonymous, many of whom had hit the bottom rung of the medical, social, and economic ladder. Their present membership has an annual estimated earning capacity of \$150,000,000.

MUNICIPAL RESPONSIBILITY

The effects of problem drinking on the security, productivity, and stability of our communities can be measured by a number of factors. The incidence of disease among these people is high. Their accident rates in the factory, the shop, and the home are abnormally high. Their rates of absenteeism and turnover and unemployment are marked. Their marriage rate is lower. Their divorce rate is higher. Eighty to 90 per cent of the population of municipal and private shelters comprise problem drinkers. The damaging and frightening effects of problem drinking spread out and affect the child of the alcoholic parent, the wife, the brother, the employer or the employee.

Private agencies by themselves cannot

be expected to cope with problems as numerically large and cross-sectional as these. These are clearly in the public domain. As a public liability, they are a public responsibility. Only within recent years has government taken action to meet these problems squarely. At the present time eight states have official commissions on alcoholism. Many local communities are likewise taking official action to explore and meet these problems.

In the State of Connecticut certain funds have been set aside to be used for the study, treatment, and care of problem drinkers. Other states and communities are proposing to establish facilities for problem drinkers. There is much confusion, however, in the minds of interested people in communities as to how to prepare laws and legislation relative to the handling of problem drinkers. Unless guidance is forthcoming from the medical profession and public health officials, it is possible that large amounts of public funds will be injudiciously allocated and expended without knowledge of the actual needs and without proper consideration of public health procedures necessary to cope with the problem.

The New York Academy of Medicine Survey of facilities for the Care and Treatment of Alcoholics reported: "A feeling of frustration seems to prevail in the attitude of most of the social agencies. Neither the Welfare Council of the City of New York nor the Mental Hygiene Committee of the State Charities Aid Association, nor any other similar agency has developed any constructive program as to methods of dealing with the problem."

The Chief Magistrate points out that the "whole subject of alcoholism, particularly in its relationship with penal sanctions and their enforcement by the courts, needs a thorough overhauling and an approach not yet adequately undertaken, together with provisions for

facilities of substantial and permanent character. He stresses the lack of adequate facilities for the treatment of alcohol addicts and says that without some medium, such as a farm colony where large numbers of cases could be assembled for a scientific approach to the problem, the courts are helpless to deal with the problem in a constructive manner.

"The Department of Education of New York City is frequently faced with the effect of parental alcoholism on the behavior and attendance of the students. The Bureau of Child Guidance of the department has to meet as best it can the problems arising among children coming from homes where one or both parents are chronic alcoholics. These children present all kinds of problems from aggressive behavior to truancy and delinquency.

"The Division of Vocational Rehabilitation of the New York State Education Department has given a great deal of thought to the rehabilitation of alcoholics. It accepts this group for vocational rehabilitation and pursues a policy of studying individual cases with regard to the cause and type of alcoholism—whether it is chronic or intermittent, and the like. It is guided, to a considerable extent, by the medical information that is secured from the individuals' physicians. The division, however, has not as yet developed any special training facilities for alcoholics but it reports that it is in a position to arrange for psychiatric treatment for some of them where the medical information indicates a favorable prognosis.

"The City Health Department recognizes alcoholism as a matter of public health concern but has never had funds for the establishment of a program to deal with it. In writing to the committee Dr. Ernest L. Stebbins, the former Health Commissioner, expressed his judgment that alcoholism should be regarded as a public health problem, and

that it should be possible . . . 'to approach the problem through agencies providing public health education, the establishment of diagnostic clinics affiliated with a referral agency, and the provision of adequate alcoholic treatment centers with facilities for follow-up care.'"

A disease, whose ravages affect not only its victim, but all who are dependent upon him or in close contact with him, is clearly the concern of public health and municipal authorities. The cost of the disease to society is staggering. From 25 to 28 per cent of all crimes are estimated to be associated with alcohol. The costs to society of merely confining and punishing the alcoholic run to millions of dollars a year. According to statistics cited by Dr. George S. Johnson, Professor of Neuro-Psychiatry at Stanford University School of Medicine, alcoholic psychoses accounted for 4.5 per cent of all first admissions to hospitals for mental disease in 1938. An additional 6.9 per cent were patients suffering from alcoholism without psychosis. Arrests for drunkenness throughout the nation range from about 1,000 to 3,000 per 100,000 population. All deaths involving alcoholism as primary or secondary cause accounted for one of every 200 of total deaths for the year 1940. Prisons, hospitals, mental institutions, social agencies, would be relieved of a heavy load if alcoholism could be wiped out, as smallpox and the black plague have been wiped out. The cost to society in terms of human lives, human misery, broken homes and broken hearts resulting from alcoholism cannot be estimated.

Education on alcohol is required by law in all the elementary schools and most of the high schools of this country. However, a recent survey indicates that the content as regards alcohol education is unsatisfactory. This has happened because by far the largest part

of the course material used by writers of textbooks has come not from scientific sources, but directly or indirectly from lay groups with a specific interest. The teaching is reported to reflect anxiety that objective scientific presentation of the subject might frustrate the aims tacitly incorporated in the statutes which require education in alcohol, namely prohibition. There is required a revision of education with regard to alcohol, a clearing away of all inaccurate statements and misconceptions and the development of sound information and instruction so that one may see the problem of alcohol as aspects of the hygiene of the individual and of the society in which he lives.

SUMMARY

Health officers can play an effective rôle in assisting our local governments in the resolution of the problems of problem drinking. As health officers, as well as educators, they can encourage the people of their communities to recognize the medical nature of problem drinking. They can insist that the departments of education not only present this point of view but also utilize only objective, scientific publications on problem drinking. The health officers can impress upon their communities the wisdom, measured in medical, social, and economic terms, of utilizing and developing medical instead of penal institutions for the care of problem drinkers. Over and beyond the need for the institution of service, is the abounding need for medical facilities in which continuing research may be undertaken into the character and causes of problem drinking, effective means of treatment and prevention.

Within the framework of their local departments of health, health officers can supply a long neglected need in encouraging demographic studies of problem drinking. The data coming out of these studies are essential to the shaping

of any intelligent, long-range, community program. As much in their capacity as physicians, as in their official rôles as health officers, they can encourage agencies of government to recodify the law with a view of making

problem drinkers the charge of health agencies rather than penal agencies. And, finally, health officers can be of inestimable value in guiding legislators to develop the kind of laws necessary to cope effectively with this problem.

Alcohol Education— Its Needs and Challenges*

JOSEPH HIRSH, F.A.P.H.A.

*Associate Director, The Research Council on Problems of Alcohol,
New York, N. Y.*

THERE are estimated to be 3,750,000 chronic and excessive drinkers in the United States today¹—roughly seven times the number of tuberculosis patients. The lives of every family, business, or institution are affected by them directly or indirectly. One expert estimates the cost of their unpredictable, uncontrollable drinking to themselves and to society to be *one billion dollars a year*.²

The problem drinker is a sick person. Much that is known of his sickness is of relatively recent origin, coming largely from psychiatry.^{3, 4, 5} Much is known of his uncontrollable compulsion to drink, viewed by some as the symptom, by others as the cause, and by still others as the process, of his sickness.

The resources of experimental and clinical medicine, of public health and of education must be fully focused on the problem drinker before anything approaching an intelligent understanding and solution to the alcohol problem can be achieved. Critical reports^{6, 7} of medicine's lack of leadership in this field have finally evoked a favorable response by the American Medical Association and the American Hospital Association. Similar challenges exist for health educators.

Every state under law requires a specified number of hours of teaching

on the subject of alcohol at the elementary school level and also at the secondary level in all but four states.⁸ Such instruction is carried out in general science, biology, and hygiene classes as well as in history, civics, and social studies classes. Though all states require instruction on the effects of alcohol, only a little over half of them make any effort at guiding teachers in the content or the presentation of the subject.

Thirteen states and the District of Columbia* make available to teachers special study units as a guide to instruction. Independent of state departments of education, the local boards of education of a number of large cities publish special teaching units for their own schools. Ten states† publish courses of study in the health field in which one or more units are devoted to the subjects of drug, narcotic, and alcohol addiction. A half-dozen other states‡ provide teachers with supplementary materials as a guide in developing units of instruction on alcohol.

In the remaining states no guidance is given teachers or students either in terms of suggested units of study or

* California, District of Columbia, Florida, Kansas, Maine, Massachusetts, Michigan, Minnesota, Nebraska, New Hampshire, North Carolina, Utah, Vermont, and West Virginia.

† Arizona, Indiana, Mississippi, Missouri, New York, North Dakota, Pennsylvania, South Dakota, Washington, and Wyoming.

‡ Typical of which are Delaware, Iowa, and Ohio.

* Adaptation of the paper presented before the Public Health Education Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 10, 1947.

educational materials. School districts as well as individual schools in these states must rely upon standard textbooks in the health, biology, and physiology fields to provide basic materials to meet the legal requirements. In few, if any, of these states are supplementary materials, devoted entirely to alcohol education, made available or recommended. In other words, almost half of the states requiring alcohol education depend upon oblique and inadequate references to meet the requirements under law.

While the framework for intelligent education of emerging citizens on this important social and public health problem exists in the law in all states, the content of most of the instruction is neither comprehensive nor critical. Part of it is due to poor teacher preparation, part of it to lack of adequate instructional materials.

As an aside, it is both interesting and important to note that in eight states the Woman's Christian Temperance Union workers are specifically authorized to lecture in public schools on this subject. They are also active in the schools of a number of other states. This alone is a challenge to health educators.

Despite the large area of unknown facts more than enough authoritative sources are available for the most critical health educator in the preparation of alcohol education materials. A study of the alcohol literature—books, pamphlets, articles, and papers—almost completed⁹ reveals the existence of over 100,000 titles. Close to 80 per cent of them are largely propaganda, for or against alcoholic beverages, using in some cases, more often abusing scientific findings in an effort to make a case for or against alcohol. Twenty thousand titles may be said to constitute the bulk of the objective alcohol literatures. Yet many of these, 30 per cent according to one estimate,¹⁰ are

compilations: 10 per cent are duplications, popularizations, reformulations, or republications. The bulk is therefore reduced to 12,000 titles. Fully half of the 12,000 titles deal with medicolegal, sociological, historical, and administrative problems. The seeker of scientific facts in the literature is therefore left with some 5,500 titles reporting original studies on the biochemical, pathological, physiological, psychiatric, and psychological aspects of problem drinking. Of these, 2,000 are dated and obsolete, leaving 3,500 titles—adequate for some, apparently not enough for most writers and teachers. For a review of the more recent popular books and articles (including health education materials*) indicates that in their preparation, few, if any, of these select titles were consulted. *Secondary sources and the propagandistic literature apparently were the chief references.* Here then is another issue which health educators cannot leave unchallenged.

Almost half of the textbooks used in elementary and high schools throughout the country in which the problems of alcohol are mentioned, or form an important part, are in the fields of health, hygiene, and physiology (biology). Less than a quarter are in the field of the social studies. The remainder are scattered in a number of other disciplines. To date, there is not a single adequate textbook on the primary or secondary levels or for the general public entirely devoted to this subject in a completely comprehensive and scientific fashion. Nor do the existing texts containing alcohol information fully meet critical requirements.

A number of critical studies have been made of health education texts,¹¹ physiology and hygiene texts,¹² and

* Health and hygiene books and pamphlets, biology and social studies texts containing references to the alcohol problem.

biology and general science texts,¹³ containing alcoholic information. The most comprehensive of these¹⁴ covers a wide variety of elementary and high school textbooks in the aforementioned fields as well as in civics, citizenship, and social studies. After a review of these texts, the author cogently and challengingly comments on the sources of the alcohol material:

The largest part of it comes from publications of temperance organizations . . . (and) such reports by medical men as seemed to offer the best support for the doctrine of total abstinence. The influence of such a publication as the *Syllabus in Alcohol Education* of the Woman's Christian Temperance Union, for example, has been outstanding. Some of the state publications appear to have been largely derived from it. Other publications of the same organization, as well as those of the Scientific Temperance Federation, have also been widely quoted and paraphrased. Apparently few textbook writers have gone to original sources, and even those who quote scientific experiments tend largely to rely upon these other groups to predigest the material for them.¹⁵

In the interests of science, of truth and of democracy, such a situation is untenable. In order to attack it intelligently, it is important to understand how it came into being.

In the first place, temperance organizations were largely responsible for alcohol education being required by law. That school boards and publishers should have deferred to these organizations in the matter of instruction was a natural though unhealthy consequence. It can no longer remain unchallenged. Furthermore, there has been the frank lack until recently of adequate compilations of scientific source materials for the use of textbook writers. These materials are now becoming increasingly available and it devolves upon the teachers of future teachers and the writers of elementary and secondary textbooks to use these unbiased source materials adequately.

The existing textbook material in the field of alcohol education, derived as it is largely from secondary sources and from sources of valued and restricted judgments inevitably perpetuates stereotypes, moral judgments, errors and conclusions which are often scientifically unjustified. The presentation of the physiological facts in regard to alcohol—the most completely scientific area in this field—leaves much to be desired. As many errors are made concerning the pathologic effects of alcohol upon the body as there are frank misrepresentations of its social effects. The psychology of drinking habits is permeated with casuistic conclusions. Not a single presentation of any facet of this problem is free from criticism. This applies equally to health and hygiene, biology and social science texts.

The responsibility for correction of this situation rests with state and local boards of education who have unquestioningly accepted educational materials of valued judgment, with the colleges neglecting to prepare teachers adequately, with the publishers who accept uncritical textbooks, with the scientists who, until recently, have not made source materials available for the textbook writers and have failed to encourage the preparation of sound educational materials. Finally and most pointedly, the fault lies also with health authorities and health educators who, with few exceptions and until relatively recently, have failed to address themselves to this important public health and educational problem.

While drinking excesses and efforts to control them have been common throughout history, the problems of alcohol as we know them are of recent vintage. During the past two and a half centuries, since the distillation process graduated into an important industry, confusion and controversy have dogged these problems. If equitable solutions are to be achieved and

the problem drinker is to be cared for as a patient, our students through our schools and the public in general must be exposed to new patterns in alcohol education that are sound in fact and unbiased in spirit.

Scientific and medical teachings must replace the moralistic preachments as in other public health problems—the venereal diseases, mental illness, tuberculosis, even cancer—if progress is to be made. The principles of a handful of non-partisan private and public agencies operating in the alcohol field* may serve as a useful guide.

Alcohol education holds three basic challenges for educators in general and health educators in particular. First, it is a field of ever-increasing knowledge untitled by trained, objective persons. Implicit in it is the solution of a complex socio-medical problem, problem drinking. Second, although it is required teaching under law in practically every public school in the United States, teachers are little prepared to render such instruction. For want of adequately trained personnel and of instructional materials for teachers and students, departments of education in some cases are forced to take what they can get, in other cases actually choose teachers and materials of valued judgment because they have dominated the field so long. Third, many instructional materials are inadequate in content, haphazard in presentation and interpretation, and of limited scientific value.

Health educators and health authorities have a continuing responsibility to address themselves to these challenges and to present the facts about alcohol and its effects in precisely the same terms as they present any other subject—objectively, completely. Anything less necessarily perpetuates errors and falsehoods, delays an intelligent solution of the problem, prolongs half-hearted social action and results in the waste of incalculable thousands of dollars of public funds presently being appropriated for medical and educational programs in this field.

Rural Prepayment Medical Care Plans and Public Health Agencies

MARK ZIEGLER, M.D.,* E. RICHARD WEINERMAN, M.D.,†
AND MILTON I. ROEMER, M.D., M.P.H.‡

*Health Services Section, Farmers Home Administration,** Washington, D. C.*

MOST public health workers are acquainted with the medical care program for low-income farm families sponsored since 1935 by the Farm Security Administration.¹ The only federally sponsored activity utilizing the principal of health insurance, this program has provided the nation's most extensive experience in voluntary group prepayment for health services among rural people. The recent changes in agriculture legislation, replacing the Farm Security Administration with the Farmers Home Administration, do not authorize the personnel of the new agency to furnish technical guidance and supervisory assistance to these health service associations. Due to the scarcity of competent leadership among the members of many of these associations, this change will in all probability result in the discontinuance of these groups if assistance from some other source is not forthcoming.

Public health workers in hundreds of rural counties and in most state departments of health are actually in a position to help in the preservation of these group health plans and, at the same time, to increase the effectiveness of their own preventive medical work.

It is to these persons in particular—and to all others concerned with the problems of rural health—that this communication is addressed.

BACKGROUND OF THE FSA MEDICAL CARE PROGRAM

Organized activities in medical care were first undertaken around 1935 by the Farm Security Administration, as a phase of its general program for rehabilitation of low-income farm families. It was early recognized that poor health and the financial drain of large medical expenses were major reasons for farm failure. Financial plans could be made for most elements of farm and home management, but expenses for medical care could not be budgeted on an individual family basis. Group prepayment into a common fund by all interested FSA borrowers in an area was the obvious answer. Voluntary health insurance plans accordingly became the central feature of the FSA health program. Such prepayment plans were supplemented from time to time by other activities, including: (a) health centers with full-time public health nurses in resettlement projects, (b) farmstead sanitation improvements, (c) financial grants for individual medical emergencies, (d) a specially subsidized demonstration program of comprehensive prepaid medical care in selected counties,² (e) health education and

nutritional programs, and (f) a special public health and medical care program for migratory farm laborers.³

Typically, the prepayment plans have been on a county basis with an average membership of 100 to 150 farm families. The scope of services has varied in the different plans, but nearly all have provided the services of general practitioners. Depending on the ability-to-pay of the families in the area, various combinations of surgical services, dental care, hospitalization, and prescribed drugs have also been offered. The annual premium has varied with the scope of services, ranging from about \$12 to \$72 per family in different regions and in different years. Free choice of doctor has been the rule. Professional and hospital bills have been paid from the pooled fund according to an approved fee schedule. Administration has been handled by a bonded trustee or a board of directors, made up of members, with a hired manager. Negotiations with physicians, dentists, druggists, and hospitals have usually been handled by FSA medical and technical personnel, and these officials ordinarily have given continual supervision over the routine business of the plan.

The prepayment plans grew rapidly, from the eight counties reporting in 1936 to the peak of 1,131 counties covered in 1942. While the vast majority of these plans were limited to a single county, there were a few multi-county units, so that this represented 1,062 different group plans. They had a combined membership of 116,631 families, or 615,985 persons in 42 states and Puerto Rico.⁴

During the war period and immediately after, the program declined. An important reason was the overall decline in the FSA case load. Beyond this, however, the proportion of eligible borrowers electing to join plans fell from 60 per cent in 1942 to 30 per cent in 1946. Factors contributing to this were the

growing shortage of rural physicians aggravated by the war, agricultural prosperity which gave to some farm families an unaccustomed sense of economic independence, rapid wartime turnover of FSA personnel, and the inherent weaknesses of voluntary enrollment. By June 30, 1946, the number of plans had declined to 635 in 951 counties in 37 states. The combined membership was 47,356 families, or 248,010 persons. A proportionately greater share of persons came to be protected for hospitalization, while a decreasing number were covered for physicians' care in the home or office.⁵

At this point, in August, 1946, Congress abolished the Farm Security Administration and set up in its place the Farmers Home Administration.⁶ This brought about several changes. For example, FHA personnel lack authority to organize, conduct, or manage the group health plans. Although FHA still emphasizes the importance of using regular "farm and home" loans to pay membership premiums in any existing voluntary prepayment plan, it is obvious that survival of the original group health plans is seriously threatened by the curtailment of the actual organizational assistance hitherto rendered by the experienced FSA personnel.

Despite the decline in aggregate membership of the health plans during the war years, it may be noted that almost 1,000 rural counties—nearly one-third of those in the nation—still retain at least the skeletal structure of a voluntary prepayment medical care program.

The distribution of the FSA plans throughout the country and the type of service provided by each, as of June 30, 1946, is summarized in Table 1.

This is the situation confronting persons concerned about rural health today. The one most extensive rural medical care program—with widespread backing from farm groups—is seriously

TABLE 1

Rural Prepayment Medical Care Plans of the Farm Security Administration, with Membership by Type of Service † — June 30, 1946*

State	Plans	Counties Covered	Number of Persons	Type of Service: Per cent of Families Served

† In counties having two or more separate units offering different types of service the membership of the smaller unit or units has been deducted on the assumption that these families also hold membership in the larger unit.

‡ Including Puerto Rico.

in danger of disintegration unless new support is soon forthcoming. There would seem to be no more appropriate community agency to lend stability to this program than the local department of health. A number of practical reasons exist for health departments to rally to this opportunity. Before considering such reasons, however, it should be made clear that this would not be the first occasion for coöperation in this program between agricultural and public health agencies. Although the central task of building prepayment plans has been

directly assumed by Farm Security personnel, there have been a variety of activities in the sphere of preventive medicine and sanitation in which coöperation between FSA and public health personnel has for many years been successfully undertaken.

PUBLIC HEALTH COÖPERATION IN PREVENTIVE SERVICES

The basis for close working relationships between agricultural and public health agencies was laid early by the assignment of U. S. Public Health Serv-

ice personnel to the Department of Agriculture to assist in the development and operation of the program. Such assignments were both in the Washington office and in the field, and they included medical, dental, engineering, and statistical personnel. A number of administrative personnel, moreover, came from backgrounds in public health work. The Chief Medical Officer of the entire program has always been a commissioned officer of the Service, making periodic reports to the Surgeon General.

The Farm Security Administration was keenly aware of the importance of preventive services to complement its prepayment medical care plans. This was expressed by construction and educational programs in environmental sanitation, intensive planning in the agricultural and home aspects of nutrition, family education in personal hygiene, and encouragement in the utilization of health and welfare services of all local agencies.

Between 1937 and 1942, some 100,000 farm families in 1,023 counties of 45 states had been assisted in the physical improvement of their sanitation facilities. Over 92,000 sanitary privies were built, almost 50,000 family water supplies were protected, and more than 58,000 dwellings were screened. This was made possible by cash grants from the FSA, but all construction was in accordance with the standards of the state and local health departments involved.⁷

Except in Puerto Rico, where community water supply projects continued to be financed, grants for construction were discontinued after 1942. Efforts to improve farm sanitation, however, did not lapse. They took the form of cooperation with public health authorities in educating FSA borrower families about the importance of making improvements in their sanitary facilities largely through their own resources. Sometimes loans were made to help

finance the purchase of materials. In North Carolina, for example, there was a long series of meetings of FSA families with public health personnel devoted to instruction in farmstead sanitation requirements. Scores of local projects resulted from these educational efforts. In Nebraska, Kansas, Montana, Wyoming, and Colorado, sanitary engineers of the state public health agencies trained FSA personnel in the elements of farm sanitation, so that the information might be passed along to farm families. Similar activities in the states of the Pacific Northwest resulted in 121 major sanitary improvements on farmsteads in that area in 1946 alone.

A variety of projects were carried out to make available to FSA families the special preventive services offered by health departments. Such efforts were useful in complementing the treatment services available through the prepayment plans. In Louisiana, for example, FSA families in several parishes were given stool examinations to detect hookworm infestation, blood tests for syphilis, and immunizations against diphtheria. FSA personnel organized the presentation of specimens or attendance at clinics, and public health personnel rendered the technical service. In one county of Arkansas, the water supplies of FSA families buying their own farms were systematically tested. In another, a county public health nurse—together with a FSA Home Management Supervisor—visited all FSA families presenting troublesome health problems. In another county, arrangements were made for all expectant mothers in FSA families to attend a local prenatal clinic. In Clay County, Arkansas, 181 FSA farmhouses were sprayed with DDT by local public health workers and 1,150 typhoid immunizations were given in 1946. Immunization clinics were organized for children of FSA families in Nebraska. For years, public health nurses have addressed meetings of FSA

families in Michigan. Health educational literature, prepared with the assistance of public health workers, has been sent to FSA families in Arkansas, Nebraska, California, and Oregon. A four-parish program in health education was sponsored jointly in Louisiana in 1945 by the state departments of health and education and the FSA, using a full-time health educator. The FSA offices in Ohio, Washington, Colorado, Indiana, and other states have pioneered in the distribution of "guide books" containing information about all the health services available in the state.

Much of the coöperation has been through interchange of information between the field personnel working in the two programs. Public health officials in Nevada and Utah, for example, participated actively in training conferences for FSA county workers, thus equipping them to deal more effectively with health problems among the farm families they serve. In Mississippi, especially successful training courses were conducted by state public health personnel for FSA Home Management Supervisors in 1946, and for all FSA county workers in 1947. This instruction has equipped FSA workers better to deal with problems of maternal and infant care, nutrition, sanitation, infectious diseases, and other health matters which they meet in their daily contacts with farm families. Joint meetings of FSA and public health workers on many different subjects have been held in Minnesota, North Dakota, Ohio, Indiana, and other states.

In a few selected areas, where the Farm Security Administration sponsored and subsidized demonstration programs for improved rural medical care, relatively close and continuing relationship with public health authorities has been enjoyed. This was the case, for example, in Walton County, Georgia, where a grant-assisted prepayment plan for all interested farm families (not solely FSA borrowers) has been sponsored by the

Department of Agriculture during 1943-1946. The county health department here coöperated continually in the operation of this plan. A unique medical care program in Taos County, New Mexico, utilizing salaried personnel working in health centers, had the regular support of state and district public health groups in that state. Coöperation in the provision of nursing services to members of an FSA subsidized prepayment medical care program in Southeast Missouri was offered by the state public health authorities of that state. In 1947, a prepayment plan, with all services to be rendered through a community health center, was undertaken in Costilla County, Colorado. The Colorado State Department of Health is preparing to coöperate directly in this program. In this way preventive and curative medicine will be physically as well as functionally united.

Many further instances of coöperative working relationships between the Farm Security Administration and public health agencies could be cited. This should be sufficient, however, to indicate that, on a nation-wide basis, the area of coöperation involving preventive services has been broad. There has been a common gain from such mutual activity. The health department has advanced its regular work and the FSA medical care program has improved the preventive content of its services. Most important of all—farm families have been benefited.

CURRENT OPPORTUNITIES FOR EXTENDED COÖPERATION

Today, an even wider opportunity for coöperation is presented to public health agencies: an opportunity for participation in the medical care aspects of the program.* As described above, the

* Even in this sphere, coöperative activity would not be entirely new. In Natchitoches Parish, Louisiana, and in a few counties of Arkansas, the local health officer has acted as the trustee of the medical care prepayment fund itself.

recent legislative and administrative changes incident to the establishment of the Farmers Home Administration now necessitate curtailment of the activities of all the full-time agricultural supervisors and have resulted in drastic reductions in the health services staff.

It is important to remember, in this connection, that FHA loans to farm families can still be used for membership payments in existing prepaid medical plans. Thus, the financial aspects of the health groups do not change; it is the professional guidance and local leadership that have been lost. It is true, of course, that the outright grants formerly made to six or seven of the specially subsidized "experimental health programs" will no longer be available and that these particular projects must undergo financial as well as administrative readjustments. But the 635 "regular" health groups have operated solely on membership premiums and will continue to do so.

Technical help is badly needed if the plans are to maintain continuing relationships with the doctors and hospitals, to make periodic adjustments in the scope and cost of services, to help devise and revise fee schedules, to manage in the handling of funds to protect the interests of the professional groups and of the farm families, and to meet all the day-to-day problems that arise in a medical care plan. The local health officer is in position to offer considerable help in such matters.

As a matter of fact, this opportunity comes at a time when participation by health departments in programs of medical care is particularly opportune. Health departments everywhere are facing the task of gaining experience in this field.⁸ The major medical care legislation before the 80th Congress, such as the National Health Act of 1947 introduced by Senators Taft, Smith, Ball, and Donnell, and the National Health

Insurance and Public Health Act of 1947, supported by the Administration, would place in existing health departments the major responsibility for administering large programs of medical care.* It is increasingly recognized that public health agencies must gain "know how" in dealing with the basic problems of this field.

A more immediate consideration relates to the requirements of the current Hospital Survey and Construction program, already a responsibility of most state health agencies. It is generally recognized that hospital shortages are greatest in the most rural sections. Yet the present federal law requires the assurance that a hospital can be properly maintained, if it is to be entitled to grant funds.⁹ The paradox is that rural communities in greatest need of hospitals are usually the least able to assure their financial maintenance. Even if this requirement were not in the law, the full utilization of newly constructed facilities would obviously be a concern of all local and state health personnel. The operation of a community prepayment plan would be perhaps the most practical approach to this problem of usage. In many rural counties where hospitals are needed desperately, prepayment plans under former FSA sponsorship have been operating for years. They can provide the basis for expansion into community-wide prepayment plans for hospitalization and possibly other health services. In many cases, this might well enable an otherwise ineligible community to qualify for needed hospital construction funds.

It will be claimed by some that far too many counties lack full-time health departments which might carry on this

* In the former bill, assignment of responsibility to public health agencies is mandatory within two years of enactment. In the latter, such assignment of responsibility to health departments is not required but is indicated as preferable "in so far as feasible."

work. Actually, the great concentration of prepayment plans, as may be noted in Table 1, is in the states of the South, where full-time public health coverage is broadest. And it is in these states that the need for hospitals and for general medical care planning is undoubtedly greater than anywhere else.

What immediate steps might a health official take to meet this challenge? First, he might express an interest to the state or local supervisor of the Farmers Home Administration. FHA is dedicated to the principle of maximum utilization by its borrowers of the services of existing community agencies. A meeting might be called, assembling representatives of the doctors and the farmers who have coöperated in the program. The directors of the local hospitals used under the plan might be contacted. Perhaps there are problems in fee-payments, in the scope of services, or other matters that bear immediate discussion. Clerical assistance is often needed and the health department may be in a position to offer it. Possibly the public health nurses and sanitarians could stimulate enrollment of new members in the plans, as they visit farm families around the county. New contracts with participating professional groups or institutions may have to be drawn up, in which the health officer could offer technical assistance.

Some member of the health department might act as trustee of the group health fund handling fiscal matters. For this administrative service, cash payment of an amount equal to about 5 per cent of the fund may be offered. Public health personnel might play active roles on the advisory and executive boards of the health associations. Health educators could inform the general public about the operations and advantages of prepayment for medical care. Local health officers could arrange to receive regular statistical reports concerning the membership, services rendered, and

expenditures of the prepayment plans in their areas.

Even where an old FSA health plan has been allowed to lapse—because of the wartime factors mentioned earlier—initiative by the local health officer might serve to revitalize it. Competent technical guidance is frequently the difference between success and failure for these rural health groups. Health departments could stimulate the expansion of the small FSA plans into full-scale community programs encompassing all sections of the population.

There can be little doubt that responsibilities of public health agencies in the field of medical care are going to expand. Already a wide variety of medical care administrative functions have been assigned to health departments, in connection with hospital planning, welfare medical services, vocational rehabilitation, rural medical fellowships, cancer control, and other fields. Opportunities for gaining experience in the administration of health insurance plans as such, however, are not readily available. The FSA health program offers one such opportunity which has the advantage of having more than a decade of progress in back of it. This program has had the repeated endorsement of the American Medical Association and has received the active support of medical and other professional groups in nearly all the states.¹⁰ Among farm people, it has won a place as a major effort to put medical services within the reach of low-income families.

Interested public health officials would find many farm groups deeply concerned with the development of more adequate rural health services. Support and assistance would be forthcoming from the large farmers' organizations that are fully aware of the rural medical care problems of the day. Support would likewise be forthcoming from the great network of county agents operating through the state agricultural extension

services and from personnel of other agricultural agencies. Many of these agencies would be greatly encouraged in their support of the rural prepayment plans by a demonstration of leadership from the health officer.

By taking the initiative to lend a helping hand in this rural health program, public health agencies can render rural people a tremendous service and, at the same time, become better prepared for the new tasks in medical care which lie ahead. Through such participation, the goal of a coördinated preventive and treatment service for all persons can be approached.

The Public Health Nurse's Contribution in the Annual Planning of a Public Health Program*

MARION W. SHEAHAN, R.N., F.A.P.H.A.

Director, Division of Public Health Nursing, New York State Department of Health, Albany, N. Y.

AN annual plan for public health in a community is an administrative tool designed to assure essential service to meet the health needs of the agency's jurisdiction.

The processes used in formulating the plan could well be the administrator's methods of control of inter-agency and extra-agency relationships. It is his justification for a budget with which to employ personnel of specified number and qualifications with the equipment and facilities essential to their work. It outlines a series of related activities in the order of relative importance. It indicates broad methods of approach, to the whole, and for component parts. It determines the pace by limiting the time for accomplishment as far as practicable. It makes possible the discipline which accompanies a plan for co-ordination and a standard for evaluation through clearly stated purposes to which the agency is committed. It gives focus to interim planning for unit programs or projects which are points of attack in a complicated design. It makes possible the exercise of personal initiative and imagination in the discharge of assigned responsibility without danger

to the fixed purposes of the agency. It gives a concrete basis for the relationship between the representative of the agency and the client to be served.

Obviously such a plan is a dynamic tool for good direction. It must lead on to wider fields and better service while keeping within a realistic goal which is possible of attainment. A wise judgment in balancing such a program is based upon: (1) A knowledge of community needs and of scientific knowledge applicable to serve them. (2) The understanding of the skills and methods essential to an organized effort. (3) An appraisal of available experiences at each point in the organization or from without, if necessary, taking in the entire range from the top down the line to the consumer. (4) An appraisal of existing personnel and facilities to determine their adequacy to do the job proposed. It may be harsh to say that those who consider it wasteful of time to plan purposefully to secure specified results, have only to examine critically those multi-service health agencies which operate on the basis of each unit for itself.

Individuals who view serious planning for public health as a threat to their security might be interested to read Barbara Wootton's book *Freedom Under Planning*.¹ While her topic is the broad one of economic planning by government as an aid to cultural free-

* Presented at a Joint Session of Public Health Veterinarians and the Health Officers, Public Health Nursing, and Public Health Education Sections of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 6, 1947.

dom, the two conditions she outlines are pertinent to our field. She states the first condition as the obvious one that "Planning must know where to stop" and second, that "planners should show a nice discrimination in their methods."

It is probably true that efficient top officials like to manage, but the number who are deliberate autocrats is surely small compared to the number who appear autocratic through failure to recognize the importance of "nice discrimination in their methods."

The new approach to planning through offices of planning, which are being established in greater numbers in large public health agencies, is a recognition that planning is an agency-wide function and that methods are being defined to secure essential contributions from all groups. This may be the answer in our field to the question, "Who Is To Plan the Planners?" which is the title of the last chapter in Miss Wootton's book.

Probably the crux of this discussion is to consider the question, "how to secure the contribution of public health nurses and to utilize it to its fullest in program planning?"

CONTRIBUTION OF THE PUBLIC HEALTH NURSES

Staff and Field Supervisors

The public health nurse and her supervisor are in a position different from that of most other workers in the public health field. Clinicians, field engineers, and sanitary officers and the social worker, if employed in the health agency share with her in services at the periphery, but more than all others she is on the proverbial firing line where a plan meets its final test. She deals directly with doctors, patients, and their friends and families, with workers from allied agencies. Here enter the human elements of freedom of choice and the

fears which may run counter to a slide rule plan, if the attitudes of the people at the crossroads are not accurately gauged. Here the details, if poorly executed, may defeat the most idealistic purpose. Distance which separates this point from the center of planning increases the danger that acts of service, while good in themselves, will become unrelated to the broad purposes to be obtained. Often with the best of intention a good plan, *per se*, fails at the seat of execution. Here is a point where staff must be kept in tune with the agency through a certain understanding of its purposes. Given that understanding, here is a group whose contribution to planning will be to give: evidence of results obtained from services rendered; evidence of needs not expressed in vital statistics; adequacy in agency procedures; an estimate of the temper of the people at the crossroads; observations as to reasons for successes or failures.

DIRECTOR OF NURSING SERVICE

The director of the nursing service is the representative of the chief officer, and as such should be the intermediary between him and the staff. She is his aide in securing the contributions of the public health nurse at each point in the line of organization, and since everyone with responsibility is a planner of a sort in his or her own right, these contributions must go both up and down the line.

The methods she will use are many and are all needed in a constant and conscious effort to make the most of the processes of planning for the good of workers. These methods are not new:

1. Periodic conferences of the whole or, as indicated, of part of the staff with the director of nursing and on occasions with the chief officer and other directors.
2. Advisory committees within the agency and from without, when indicated.
3. Interviews for spot sampling of opinions or reactions.

4. A study of tabulations from records and reports to determine service rendered and results obtained.

5. Where a large area is encompassed mail communication to and from the central office to receive and present to the staff comments and problems for their consideration.

6. A meeting for acquaintance, no matter how brief, with all members of staff, if the chief officer visits a decentralized office.

In a large agency, much of the contributions of the staff of field nurses and supervisors must be summarized by the nursing director, for everyone cannot sit at a council table. The chief officer should assure himself that her advice to him and guidance for him of the nursing service are based upon democratic participation by the staff. Her individual judgment *alone* may become narrow and misleading in planning and prove a detriment rather than an asset.

The director of a nursing service should be expected to participate in planning councils in the central office through her grasp of organization for community health in general and her specialized knowledge of nursing in particular. She should be held responsible for authoritative advice on her specialty and for making wise judgments as to how it may be used to best advantage in any given plan. She should be able to estimate the adequacy of the nursing resources, within and without the department to get the job done. Preparation, numerical strength and

distribution should enter into her judgment. She later should be responsible for the details of a nursing program within a broad plan and for establishing nursing policy, procedure, interpretation, and stimulation and preparation of the staff who give the service to implement one part or another of the plan. Participation in the discussions whereby a broad plan is formulated is her indispensable preparation to carry her responsibility when the health officer gives the order. Her participation is the health officer's evidence to the nursing staff that they have representation and that he respects their specialty and receives their contributions. The knowledge, experience, and judgment he should expect from her, are indispensable to him since nursing is one of the specialized fields of which he has only general knowledge.

CONCLUSION

Provision for staff contributions to annual planning must obviously be part of agency procedure. An administration with the attitude which such provision implies will have gone far to accomplish that coveted *esprit de corps* from which springs sustained good service, the ultimate purpose for any overall plan.

THE ATLANTIC CITY MEETING

THE Seventy-fifth Annual Meeting of the American Public Health Association at Atlantic City, N. J., October 6-10, appears in retrospect as one of the notable gatherings in the history of our Association. The registration was not large (3,208); but this was to be expected in view of the fact that the expense of living at Atlantic City is high and that in such a resort there is no large reservoir of local physicians and nurses and medical students and other interested persons, such as is drawn upon in a large city. The leaders in public health were there, however, from every corner of the North American Continent; and we were honored by the presence of four of the outstanding officials in this field from the United Kingdom, of the Vice-Minister of Health of China, and of distinguished representatives from Brazil, Cuba, Denmark, and the Netherlands; with—for the first time—members of the staff of the World Health Organization. Particularly significant is the fact that thirty-one affiliated organizations held their meetings jointly or concomitantly with our own Association and its Sections.

There was some criticism of the fact that meetings of the Association and its Governing Council were scheduled for all five days; and it may be wiser in future to return to the plan in force in the past of leaving Monday of the week free for these affiliated groups.

All the twelve Sections of the Association held from one to four meetings by themselves (one for Maternal and Child Health, four for the Laboratory Section, two or three for each of the rest). Particularly notable were the Joint Sessions, which emphasized in wholesome fashion the cross-over of interests between different sections. Nine such joint sessions were held. One on Rheumatic Fever included Maternal and Child Health, Epidemiology, School Health, and Vital Statistics. One on Preparation in Health of School Personnel brought together School Health, Maternal and Child Health, Public Health Education, Public Health Nursing, and Food and Nutrition. One on Current Status of Immunization Procedures was sponsored by the Epidemiology, Health Officers, Laboratory, Maternal and Child Health, and School Health Sections.

All in all, 322 speakers participated in the discussions and 227 papers and reports were presented. Of the high quality of these communications, our readers may judge for themselves by approximately one-third of these papers—selected

for their general appeal to our membership—which will appear in this JOURNAL during the next six months. Many of the communications read at Atlantic City will be more usefully published in the professional journals representing their special technical fields.

It was generally agreed that the two special sessions devoted to the broad topic "The Heritage of the Past—The Seed of the Future" marked high points of the Atlantic City meetings. The addresses at these sessions were made by W. P. Shepard, H. R. Leavell, Homer Folks, Lowell J. Reed, Haven Emerson, Thomas Parran, C.-E. A. Winslow, and Raymond B. Fosdick. They will be published as promptly as possible in a special volume.

The illuminating Presidential Address of Harry S. Mustard, appears as the leading article in this issue of the JOURNAL.

The award of the Sedgwick Medal to Reginald M. Atwater for "distinguished service to public health," primarily through his leadership of our own Association, added a new name to an outstanding roll of honor. The Lasker Awards, for the second year, high-lighted "men and women in the field of medical research and public health administration whose efforts have contributed to, or will in time result in, the vastly improved health status of the peoples of the earth." Oswald T. Avery, Thomas Francis, Jr., and Homer Smith received awards for scientific research in their respective fields, Alice Hamilton and Thomas Parran for administrative achievement; and group awards were made to the British Ministries of Food and Health (Sir Wilson Jameson) and to the United States Committee on Joint Causes of Death (Lowell J. Reed).

The exhibit in the Convention Hall included 130 scientific and 127 commercial displays and was of unusually high quality and interest.

The new officers, whose names were announced at the Banquet included Martha M. Eliot as President, Charles F. Wilinsky as President-Elect, G. D. W. Cameron, J. T. Fontenelle, and Emilie O. Sargent as Vice-Presidents, and Louis I. Dublin as Treasurer. Dr. Eliot and Dr. Dublin are old friends in the higher councils of the Association. The choice of Dr. Wilinsky is a happy one. His leadership in hospital administration is in line with one of the most challenging problems which confront the health officer of the future; and he has been the animating force behind the admirable district health center program of the city of Boston. Our Vice-Presidents represent not only Canada and the United States but also Brazil; and, once again, a Vice-President of the Association has been chosen from beyond the boundaries of North America.

The most important action of the Association in the administrative field was an increase in dues for the various classes of membership; and the most significant resolution adopted was one calling for the removal of artificial legal restrictions on the sale of butter substitutes which is so essential to a sound national nutrition program.

Special mention should be made of the meetings of the three Standing Committees on Administrative Practice, on Professional Education, and on Research and Standards. These committees are the vital centers of the most productive services of the Association. All three of them held long and inspiring sessions at Atlantic City.

To the Editor, there were two more general aspects of the Seventy-fifth Annual Meeting which were of far-reaching significance.

The first of these was the unity of purpose and the sense of solidarity displayed by the Joint Sessions and throughout the formal discussions and the

social intercourse of these five days. The Association includes many special fields of interest—medicine, nursing, dentistry, laboratory service, engineering, nutrition, education, and the like. Each year there has developed a closer and more cordial integration of all these separate interests in a realization of the obligation of the public health profession as a whole for a common service to mankind.

The second outstanding significance of the Atlantic City meetings lay in a permeating sense of the new problems of the future in the field of public health. No one who heard the papers and panel discussions and the addresses at the Special Sessions, no one who felt the response of the audiences to the challenges presented, can doubt where the American Public Health Association stands. It is conscious of the heritage of the past. It recognizes its responsibility for the future.

WHO IS UN-AMERICAN NOW?

ON July 2 last "The Subcommittee of the Committee on Expenditures in the Executive Departments Authorized to Investigate Publicity and Propaganda of Federal Officials in Formation and Operation of Health Workshops" made a report to the Committee of the Whole House.¹ This report has somewhat serious implications—although these implications may be somewhat different from those which the Subcommittee itself had in mind. The fact that the *Journal of the American Medical Association* has editorially summarized the report in question² warrants a study of its content.

There are essentially two sets of facts brought out in this report and used by its framers as the basis for an attack on:

1. The United States Public Health Service
2. The Children's Bureau
3. The Office of Education
4. The United States Employment Service
5. The Department of Agriculture
6. The Bureau of Research and Statistics of the Social Security Board

The first of these facts was that Surgeon General Parran on December 10, 1945, transmitted to all officers of the Public Health Service a copy of *House Document No. 380* which was President Truman's message to Congress on a National Health Program. He said in comment "Every officer of the Public Health Service will wish to familiarize himself with the President's message and will be guided by its provisions when making any public statement *likely to be interpreted as representing the official views of the Public Health Service.*" (italics ours.) Since June of that year (1945) all officers of the Service had been, by Executive Order 9575, covered into the armed forces with full military rights and obligations. Even under civilian conditions, however, such a warning as that issued in December, 1945, would have been entirely proper. The U. S. Public Health Service is a branch of the federal government, and it would be most unfortunate for any subordinate officer of that Service to "make statements likely to be interpreted as representing the official views of the Public Health Service" if those views were in opposition to those of the head of the government, whether acting as Commander-in-Chief of the Army or in his normal civil capacity.

The official views of the Service on any technical matter must be formulated by the Surgeon General himself. If his views differ from those of his official

political superiors, he can only resign. We infer from certain earlier writings of Dr. Parran that he did not feel the President's speech called for any such action. He might have taken much more vigorous steps. It would have been quite within his rights to point out that the need for some form of compulsory prepayment of medical costs is as important for the health of the American people as is the need for vaccination against smallpox. He did not follow any such course; he merely acted to protect the Service against the danger of possible criticism, by members of the federal family, of the policies advocated by the Chief of State.

The second mare's nest uncovered by the Subcommittee is the fact that between November, 1945, and November, 1946, a series of 26 "Workshops" were held in various parts of the country, under the auspices of the Service, for the discussion of problems relating to medical care. We deplore the word "Workshop"; but it has become a routine part of educational lingo. In any case, groups of citizens and experts in various areas of the field were convened and federal employees participated in the discussion of methods by which the important issues concerned could be brought before interested groups, so as to stimulate thought. The Subcommittee concludes that these discussions were planned "subtly to generate public sentiment in behalf of what certain witnesses and authors of propaganda refer to as socialized medicine." By the by, the Subcommittee is very fond of this phrase "what certain witnesses and authors of propaganda refer to as socialized medicine," repeating it half a dozen times. It puzzles us a bit. In the language of bodies like this Subcommittee, "propaganda" usually means the other fellow's argument; and no person well informed enough to discuss health insurance intelligently ever uses this phrase "socialized medicine" which has no intellectual content and is used only to stimulate the endocrines. There seems no valid reason why technical experts in the government service should not meet with groups of interested persons to discuss pressing public health problems. It is an important part of their duty to do so. No convincing evidence is adduced of the subtle generation of public sentiment; and whether we like the word or not, the "Workshop" is about as good a medium for democratic discussion as has yet been devised.

All this is pretty small potatoes for the activity of a group of representatives of the American people, convened in a Congress which faces the gravest world problems which have ever confronted the nation.

Even more serious, however, is the last paragraph of The Subcommittee report. "Suffice it at this time for your committee to report its firm conclusion, on the basic evidence at hand, that American Communism holds this program as a cardinal point in its objectives; and that, in some instances, known Communists and fellow-travellers within the federal agencies are at work diligently with federal funds in furtherance of the Moscow party line in this regard."

As to the Moscow party line, the members of The Subcommittee will perhaps be interested to learn that the U. S. A. and U. S. S. R. are the only two leading countries of the world which do not have some system of compulsory health insurance. They do not have it in the Soviet Union because they have a system of state medicine (which is radically different). For the United States to adopt such a plan would be to follow London, Paris, and the capitals of Holland and Sweden and Norway and Denmark—in direct opposition to Moscow.

As to the business of fellow travellers, the actual evidence which The Subcommittee has been able to collect is as follows. If it had any better evidence it would, no doubt have welcomed it. The facts submitted were as follows:

a. An obscure member of the staff of the Social Security Board "has been documented by the House Committee on Un-American Activities for almost uninterrupted association, since 1939, with various Communist and fellow-traveller organizations in the United States" according to The Subcommittee. How far such "documentation" may be justified we have no means of knowing. There is no evidence that he was ever condemned by any court; and it is easy to accuse.

b. It was once suggested in an office memorandum of the Security Board that this individual might be sent to New Zealand to study its health insurance program.

c. The Social Security Board "maintains close contact with movements for compulsory health insurance in other countries."

d. Another employee of the Social Security Board once assisted Senator Wagner in drawing up a health insurance bill.

e. Therefore, the Social Security Board is a Communist-front organization.

f. Much of the literature used in the "Workshops" was prepared by the Social Security Board. (This could scarcely help being the case since the studies made by this Board furnish the most authoritative statistical data we have, with respect to medical economics.) Unfortunately for the clarity of The Subcommittee's conclusions, neither the suspected Communist nor the head of Research and Statistics participated in the "Workshops."

But (g) since the "Workshops" used literature prepared by the Social Security Board (which had a humble employee accused of being a fellow-traveller) the U. S. Public Health Service which sponsors the Workshops must be tainted.

And finally, (h) since employees of the Children's Bureau, the Office of Education, the U. S. Employment Service, and the Department of Agriculture sent representatives to the "Workshops" they are probably "fellow-travellers" too.

On this House that Jack Built (or shall we say that Jerry built?) The Subcommittee bases its conclusion that "Known Communists and fellow-travellers with the federal agencies are at work diligently with federal funds in furtherance of the Moscow party line." Six bureaus of the federal government are pilloried because one employee of one of them has been charged with being a fellow-traveller, and the Attorney General has been officially asked to prosecute offending employees for taking part in "Workshops" mentioned. The true motivation of The Subcommittee is, probably, a quite different one. It appears to assume throughout that advocacy of health insurance is *ipso facto* an evidence of Communism. If this be the case, President Truman should be impeached for his message of 1945; and, since the 79th Congress did not condemn his address as emanating from Moscow, all its members must be considered as "fellow-travellers." Indeed, the 80th Congress might deserve the same designation, since its members sit in the same Chambers with many who supported the Wagner-Murray-Dingell Bill and who must be *ipso facto*, Communists.

The final paragraph of the report of the Subcommittee is the text for a shocking circular sent out to all physicians and dentists by the National Physicians Committee. It makes those who respect and love the medical profession somewhat heartsick to see the names of 13 physicians (most of them of outstanding position in the American Medical Association) at the head of this broadside.

We have no sympathy with Communism as a political movement. We believe that it is necessary to protect the United States against the influence of such citizens of our country as may hold secret allegiance to any foreign power. The *spirit* of Totalitarianism is, however, even more dangerous than its puny human

emissaries. If we adopt the methods of totalitarian ideology we are surrendering to the very worst element which is common to both Communism and Fascism. That is what is happening when we demand absolute conformity with the social program of one group which happens for the moment to be in power; stifle discussion, call everyone who differs a Communist and everyone who has ever been associated with any organization in which there was ever a Communist member, a fellow-traveller. Such an attitude abandons reason for ideology, and philosophy for perverted semantics. It overwhelms empirical evidence in a flood of catch-words. It enthrones emotion above reason, by discovering "Un-American art" and "Un-American Music" and "Un-American Science."

The writer of this editorial has behind him ten generations of New England stock. He learned that the American tradition meant freedom of thought and of speech (up to the limit of legally prosecutable action); that it meant open-mindedness and readiness to try experiments; that it meant initiative in the working out of the problems of society; that it meant experimentation and progress.

The other road—that of rigid conformity with the theory of a temporarily powerful group—of defining not only what a man must do but what he must think and feel—and with whom he may be acquainted—is the road to what is truly "Un-American." This was the technique of the Hitler regime in Germany and is the technique of the Communist leaders in Russia. Pray God, it may never become the prevailing mood of America.

ALCOHOLISM A PUBLIC HEALTH PROBLEM?

WE are glad to present in this issue of the JOURNAL two articles on the subject of alcoholism—or what Dr. Duryea describes as "Problem Drinking."

That this is in essence a major health problem, cannot be doubted. It has been estimated by E. R. Jellinek¹ that the number of chronic alcoholics in the United States is about 750,000 (slightly under 9 per 1,000 of the adult population), with a proportion of "inebriates" perhaps five times as great.

In the second place, it must be recognized that this is a medical problem—and not solely, or even primarily, a social or a moral problem. The chronic alcoholic is a sick person, whether his other accompanying physical and emotional disabilities are causes or results of alcohol addiction. Dr. Ray Lyman Wilbur is right in saying that "fundamentally, the chronic drinker is a problem for the doctor." The writer of this editorial can recall the refusal of one leading citizen, many years ago, to contribute to a certain outpatient service because its venereal disease clinic contravened the Scriptural injunction that "the wages of sin is death." We have outgrown that viewpoint in our social hygiene program. It still dominates our thinking about alcoholism; and this is the chief reason why the particular group of sick people under discussion is either wholly ignored or treated with stupidity and barbarity.

Third, this is a problem which we cannot dismiss as outside the range of human action because there is nothing that can be done about it. The success of "Alcoholics Anonymous," with its 35,000 members is proof to the contrary.² It is very probable that most of the readers of this editorial have members of that organization in their own circle of acquaintance. The Yale Plan Clinics at New Haven and Hartford have demonstrated the great value of a sound psychiatric approach in dealing with alcoholism.³ The State of Connecticut has been so much impressed that in 1945 it established a special Board of Trustees of a State Fund for Inebriates.⁴ Through the use of clinics and other facilities, it is "to provide diagnostic and treatment services for alcoholics, to study the problems of alcoholism and to disseminate information on this subject." The Board is supported by allocation of nine per cent of the fees received for permits by the Liquor Control Commission of the State.

Chronic alcoholism would thus seem to qualify as a public health problem on the ground of its social magnitude, its essentially medical nature and the fact that promising practical scientific methods of attack are now available.

The Health Officer cannot be expected to establish a new Bureau for the Control of Chronic Alcoholism. He cannot be expected to plan the exhaustive researches necessary before this problem can be wholly solved. But there are three things which he can do—and, we believe should do—in preparation for the day when the disease of alcoholism can be treated with the adequacy which it deserves:

1. He can ask his statistical service to collect such data as are available locally in regard to the local incidence of alcoholism and its relation to other characteristics of the population.

2. He can familiarize himself with existing facilities for diagnosis and treatment in this field and use his influence to secure the development of outpatient and inpatient services comparable to those now provided for most other diseases.

3. He can make every effort to influence the school system to replace outworn and tendentious propaganda by modern scientific knowledge in connection with this vital medical problem. The evidence presented in this issue by Mr. Hirsh is an urgent challenge to such a reform.

Credit Lines

"MODERN SEWAGE TREATMENT"

This is the title of an attractive brochure prepared by the General Electric Company. As with their film, "Clean Waters," an effort is made to present the subject in a manner that will appeal to the average citizen but at the same time be technically correct. It should serve a useful purpose for anyone trying to interest "town fathers" and civic leaders in the need for adequate sewage disposal. The booklet is looseleaf so that the few pages having specific commercial references can be removed easily if desired. Although not stated, copies probably can be obtained from the General Electric Company, Schenectady, N. Y.

WHO BETTER DESERVES IT?

The American Medical Association has announced that on January 7, 1948, it will award the first annual Gold Medal for "a general practitioner who has rendered exceptional service to his community." The A.M.A. will receive nominations from state medical associations, chambers of commerce, woman's clubs, community councils, service clubs, etc. It asks that with each nomination be included the physician's name and address, his scholastic record, and a record of his service in the community.

Address the Section on General Practice of Medicine, A.M.A., 535 North Dearborn Street, Chicago 10.

NEW PEDIATRIC JOURNAL

The American Academy of Pediatrics will publish a new monthly journal, *Pediatrics*, beginning in January, 1948, containing original articles on clinical pediatrics, nutrition, genetics, preventive medicine, psychology, nursing and medical sociology, education and social wel-

fare of children. A special section will be devoted to Latin American countries, where the academy has a program in operation. Abstracts of all original articles will be published in Spanish. Matters of interest in Congress, government departments and agencies in Washington will be reported. Communications of an editorial nature should be addressed to the editor in chief, Hugh McCulloch, M.D., 325 North Euclid Avenue, St. Louis 8. Advertising matter and subscriptions should be sent to Charles C. Thomas, publisher, 301-327 East Lawrence Avenue, Springfield, Ill.

COMMUNICABLE DISEASE CENTER PROGRAMS

A copy of "Schedule of Field Training Programs, January 1-December 31, 1947" of the U. S. Public Health Service, Communicable Disease Center, Atlanta, Ga., and coöperative agencies, was received recently. Prepared by the Training Division of C.D.C., it describes briefly the 14 training schedules available. The foreword makes the general observation, "The Training Division is especially anxious to emphasize the practical field training nature of these programs. Field training experiences are designed to supplement academic instruction." The area of instruction covered goes from a program for senior laboratory staff members and directors to one on primary sanitation field training.

R. A. Vonderlehr, M.D., is Medical Director in Charge and E. S. Tisdale, is Chief, Training Division of C.D.C.

HEALTH EDUCATION FOR RURAL TEACHERS

During the summer of 1947, a three

week health education course for rural teachers was given at the Pennsylvania State College with the coöperation of the Pennsylvania Department of Health and of Public Instruction. Attended by 68 rural school teachers from selected areas of Pennsylvania where follow-up supervision will be provided, it was designed to make clear the scientific bases for health and their practical application to rural schools. Scholarships were provided by various state and local voluntary health agencies, chiefly tuberculosis and health associations. The program should be helpful to those planning similar conferences in other rural areas.

SOME WISE WORDS ABOUT IN-SERVICE TRAINING

"Effective public health work calls for trained people," is the way George T. Palmer, Dr. P.H., introduces a very sensible and stimulating article on in-service training of health department employees. Originally presented before the Health Education Conference of the Western Branch, A.P.H.A., it is now available in the July 15 issue of *California's Health*. This is the semi-monthly organ of the California State Health Department where Dr. Palmer is Consultant in Public Health Administration.

LATIN AMERICAN INTEREST IN LOCAL HEALTH UNITS

Interest of Spanish speaking people in the concept of local district health units is evidenced in the June, 1947, *Boletín* (the Municipal Digest of the Americas) published in Havana. The lead article is a Spanish translation side by side with its English original, of selections from "Health Security Begins at the Local Level" published originally in a special public health number of *State Government* (February, 1946). This article discusses the need for modernizing local government in relation to local health services. Written by its

research assistant, Martha Luginbuhl, it is based upon *Local Health Units for the Nation*, the report of the A.P.H.A. Subcommittee on Local Health Units, prepared by its Chairman, Haven Emerson, M.D., and published by the Commonwealth Fund in 1945.

THE AMERICAN STATISTICIAN MAKES ITS BOW

With the August, 1947, issue (Vol. 1, No. 1), off the press in time for the 25th session of the International Statistical Institute meeting in Washington in September, the American Statistical Association started publication of a new bi-monthly journal, *The American Statistician*. Successor to the A.S.A. *Bulletin*, its avowed purpose is "to implement the growth of American statisticians . . . not a substitute for the Association's technical publications . . . but an adjunct to them, and an aid in professional development.

The first issue has a historical article on Lemuel Shattuck, founder of the American Statistical Association, and known to public health workers as the father, also, of official state boards of health following his plan for a Sanitary Survey of Massachusetts in 1850.

The author of the article, Walter F. Willcox, Professor Emeritus of Cornell University, reminds his readers that Shattuck and Ralph Waldo Emerson chose the older and shorter word, *statist* and eschewed the modern tongue-twisting *statistician*. Professor Willcox suggests that "lesser laborers in the same vineyard revive their practice."

SEX EDUCATION IN OREGON

"Sex Goes to School in Oregon" appears in the September *Better Homes and Gardens*, a monthly farm magazine published in Des Moines, Iowa. It tells just how the schools of Bend, a typical Oregon agricultural town of some 10,000 persons, are the laboratory in which the mandatory state-wide program of health

and physical education through the 12 grades will work.

Family life and sex education are taught along with the three R's and with no more fanfare. An important part of the article is the story of how the community was prepared for what might have seemed a radical departure. Oregon's state-wide education program is said to be the most extensive among the states.

ANNUAL REPORTS

Cook County's Department of Public Health annual report for 1946 is distinguished by its pictorial and graphic representation. There is a minimum of statistical data, none of it labored. Each page starts with a classic quotation ranging from Gladstone to the Proverbs. The back cover is a pyramid of healthful living which includes school health, improved housing, recreational facilities, and professional education, among others more generally recognized as health department functions. It is good to know that a health department recognizes its client as a total individual in this way. This report has much to suggest to those struggling to find new ways to tell old stories in annual reports. Edward A. Piszczek, M.D., is Cook County Health Commissioner.

"And This Is What We Did! . . . in 1946" is the title with which the 1946 annual report of the Columbia County (N. Y.) Health Department announces itself, and it proceeds to tell in simple readable language just what was done in the 14th year of this county's full-time health department. Sue Thompson Gould, M.D., was County Health Commissioner during the period of the report.

MICROFILM SERVICE OF ARMY MEDICAL LIBRARY

The feature exhibit of the 5th International Congress of Pediatrics held in New York City was a display of the

newest examples of microfilm duplication of the nation's greatest collection of medical literature sponsored by the Army Medical Library, Photo-duplication Division.

The Army Medical Library in Washington now has a collection of more than 1,000,000 volumes, some of the items going back to medieval times. These have been gathered and catalogued since 1836 when Surgeon General Joseph Lovell began the work during President Andrew Jackson's administration.

Through the microfilm service of the Army Medical Library, facsimile replicas of any of this material may be secured by physicians and libraries almost anywhere in the world. In 1946, 6,000,000 pages of medical literature were distributed on 551,102 feet of microfilm.

Articles in medical periodicals are duplicated for 50c each; books for 50c for each 50 pages or fraction thereof.

WORTH ACQUIRING

These Services are Available to You is a little pamphlet prepared by the Seattle City Health Department to tell citizens what services their health department can offer. A good medium both for getting the services used and for keeping public support. City Health Department, Seattle, Wash.

The Story of Johnny and Mary, subtitled "Better Food Makes for Better Living," is designed for the upper elementary grades. Recently published by the University of Florida. Sloan Project in Applied Economics (Gainesville, Fla.), it is good material for teaching proper nutrition and its significance for health to school children. At about the same time, the Florida Health Department issued its Nutrition Survey number, July, 1947, which makes a good companion piece to *The Story of Johnny and Mary*.

Modern Food Magic, published by the Hartford Nutrition Committee, tells in simple words how to perform miracles

in your kitchen—stretch the dollar and still keep the family well fed, happy, and healthy. One whole page tells how to “cheat the garbage can.” Available from the Greater Hartford Community Council, 17 Lewis Street, Hartford, Conn. at 8c each or 7c each in lots of 1,000 or more.

“Slidefilms and Motion Pictures—To Help Instructors” is the title of a new catalog of selected visual teaching aids produced and distributed by the School Service Department of the Jam Handy Organization. This booklet lists discussion slidefilm kits, sound slidefilms, and educational sound motion pictures for vocational training and classroom use. Subjects have been selected for timeliness and adaptability to current

teaching trends and instructors’ needs. Copies of this catalog may be obtained from the Jam Handy Organization, 2821 East Grand Boulevard, Detroit 11, Mich.

Make Your Town Safe!—This most recent of the Public Affairs Pamphlets, by Herbert Yahraes, is a valuable summary of accident figures, how they can be reduced, and the organization of a community accident prevention program. Its illustrations, though dealing with gruesome matters, are on the light side and very effective.

Available from the Public Affairs Committee, Inc., 22 East 38th Street, New York 16, at 20 cents per copy. Quantity rates are available on application.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

The Years After 50—By Wingate M. Johnson, M.D. Foreword by Morris Fishbein, M.D. New York: McGraw-Hill, 1947. 153 pp. Price \$2.00.

Dr. Morris Fishbein, who is editor of the Whittlesey House Health series of which this is one, could hardly have found a better author for this volume than Dr. Wingate Johnson. He is a distinguished physician, Professor of Clinical Medicine at the Bowman Gray School of Medicine, and recently designated a trustee of the American Medical Association, but, more important still, the volume reveals such wisdom and philosophic understanding of human beings as is given to not many men. Added to this, it is a rare treat to come across a literary style that is as delightful as this. Dr. Johnson has proved that sometimes a busy physician can beat the professional writers at their own game, and what's more he has achieved the happy combination of good writing and strict scientific accuracy.

The purpose of the book is to help the intelligent man and woman prepare for the latter half of life. It will also prove helpful for those laymen and physicians who have the responsibility of caring for the aged, whether it be a dependent on the one hand, or a medical practice on the other.

On only one minor point does the reviewer fail to go along with the author. Dr. Johnson stresses the importance of mental exercise to keep this faculty keen, but he reveals perhaps his own predilection, and age (plus 60), in minimizing the importance of keeping the physical faculties in trim. The reviewer likewise may be disclosing his

inclination and age (minus 45) in believing that moderate and regular exercise is equally desirable to preserve muscular and vasomotor tone from atrophy. It seems to the reviewer that those whose muscles and cardiovascular responses are flabby through lack of use are not in good fettle to respond to the stress of emergencies and severe illness, and they are the ones that often slowly fade out for no good organic reason under such conditions.

THEODORE G. KLUMPP

The Acute Infectious Fevers: An Introduction for Students and Practitioners—By Alexander Joe, M.D. Philadelphia: Blakiston, 1947. 276 pp. Price, \$4.50.

This small volume, as the subtitle implies, is intended primarily for medical students, and as such does a fine job of summarizing current British medical practice with respect to a dozen of the more common communicable diseases. There are few aspects of these diseases with which the author has not had a good deal of personal experience, and, as stated in the preface, he has firmly resisted the temptation to write on subjects not covered by this experience. Thus, for example, poliomyelitis, the dysenteries, the encephalitides, the Rickettsial infections, infectious hepatitis, influenza, and many other equally important communicable diseases are not even mentioned.

However, despite the lack of broad coverage in subject matter, the detailed discussion of each disease considered (streptococcal infection, diphtheria, pertussis, meningococcal meningitis, ty-

phoid, measles, chickenpox, smallpox, mumps, and rubella) is for the most part excellent. It is a pleasure, indeed, to find a medical textbook which occasionally cites references to articles published within a year of the appearance of the text itself. Thus, brief mention is made to most of the important recent contributions to our knowledge of these diseases.

Particular attention has been devoted to a description of the clinical course, to diagnosis and treatment; however, the epidemiology and prevention are given careful and concise consideration. In general the author's opinions in these matters conform closely with those held by workers in the United States. One is impressed again by the extent to which we in this country are indebted to the British for a large share of our knowledge of these diseases. Nevertheless, most of us on this side of the Atlantic would quarrel with Dr. Joe's recommendation concerning the best time for primary active immunization against diphtheria—that it "should be carried out as early as possible after the first birthday"—and would hardly agree to his statement reflecting current British opinion that, "It would be wise to regard specific prophylaxis in whooping cough as still in the experimental stage." Despite such points of disagreement and certain omissions, this text can be highly recommended. ROBERT F. KORN

Studies of Typhus Fever—*National Institute of Health Bulletin. No. 183, U. S. Public Health Service, 1945. 110 pp.*

This pamphlet consists of 9 papers representing the work of the Rickettsia Unit, Division of Infectious Diseases of the National Institute of Health, made between 1941 and 1944, much of the information being withheld from publication owing to the confidential nature of the researches. All the papers detail the various methods and results in the

preparation of epidemic typhus vaccine by the egg yolk culture method which will be invaluable to those laboratory workers concerned in this and related problems. A comparison of the vaccine prepared according to the original Cox's method and those with ether extraction was first made with the complement-fixation method, and later confirmed by the neutralization test for the lethal substance also obtained by the yolk sac culture. Both demonstrated quite clearly the superiority of the latter methods. It is therefore of special interest that by means of these newer methods for the testing of antigenicity, the value of vaccines prepared by different methods hitherto recommended by various workers against epidemic typhus fever may be systematically examined.

SAMUEL H. ZIA

The Municipal Year Book, 1947—*Edited by Clarence E. Ridley and Orin F. Nolting. Chicago: The International City Managers' Association, 1947. 550 pp. Price, \$8.50 if remittance accompanies order; otherwise \$9.00.*

This annual volume continues to be an indispensable encyclopedia of municipal activities. The current national interest in hospitals, inspired by the Federal Hospital Construction Act, is reflected in a table giving data about 266 municipal hospitals in nearly as many cities. No figures on municipal health departments such as were reported in earlier volumes are given in the current volume.

The short chapter on public health developments in 1946 by Ira V. Hiscock, Sc.D., ranges over the country and picks out many significant items that a variety of readers will want to pursue further.

The volume contains a graph showing trends of median salaries of patrolmen from 1943 to 1947. This could well be repeated in other years for other groups of municipal employees, particularly public health workers and teachers. The

chart showing indexes of cost of living and municipal salaries is also worth repeating in more detailed form.

REGINALD M. ATWATER

The Administrative Internship in the Hospital—By *Paul B. Gillen and Charles E. Prall*. Published by the *Joint Commission on Education, Chicago* (22 East Division Street), 1947.

The Joint Commission on Education is a temporary body representing the American Hospital Association and the American College of Hospital Administrators, and sponsored by the W. K. Kellogg Foundation which has also made grants to several of the university courses in hospital administration. As one of its missions, the Joint Commission has undertaken to supply curricular assistance to the authorities of the universities where graduate training in hospital administration is offered. An administrative internship of at least twelve months is required in connection with each of the existing university courses in hospital administration, and the Commission has given assistance in the planning of such internships. The manual is an important contribution to this program.

This helpful manual will be of primary interest to the faculty and students in the hospital administration courses and to the hospital administrators who are now preceptors for administrative interns or who may expect to serve in that capacity. It describes the advantages of the internship from the standpoint of the hospital and from that of the student. The educational plan for the administrative internship is presented in detail according to the student's levels of growth and development. It emphasizes the importance of a close relationship between the preceptor and the intern. The scope of the work in each department is outlined. Topics for responsible assignments are suggested.

CLEMENT C. CLAY

Blue Print for a Healthy Community—The Chicago-Cook County Health Survey. *Chicago: The Advisory Committee* (54 W. Hubbard Street). 100 pp. Price, \$.35.

This summary of a huge survey by the U. S. Public Health Service is an "audit of all health facilities in the great metropolitan area of Chicago . . . in which live 4,500,000 people."

The breadth of a modern public health program is impressive. Only ragweed control appears to have been omitted. Great and complex problems were met, as well as ones we all know—even to open privies.

The studies of dental health and medical-social work present significant advances in evaluation. The school health section makes one again acutely aware of the lack of genuinely useful indices of accomplishment in this field.

ROSCOE P. KANDLE

Anatomy and Physiology for Students of Physiotherapy—By *C. S. V. Smouts, M.D., M.R.C.S., L.R.C.P., and R. J. S. McDowall, M.D., D.Sc.* (2nd ed.) *Baltimore: Williams & Wilkins*. 470 pp. Price, \$8.00.

This textbook is a revision of one published in 1944 and is planned in accordance with the *Syllabus of the Chartered Society of Physiotherapy* in England. The older terminology is used, which might be somewhat confusing to beginning students in this country. The authors do not expect this book to replace larger texts in anatomy and physiology.

Perhaps the four most valuable chapters for reference purposes in the section on anatomy are: "Anatomical Regions"; "Living Anatomy," which has been enlarged; "Levers and Leverage," which is new; and "Muscles in Action," which defines the physical properties of muscle and types of muscular work performed. An attempt has been made to simplify anatomy, which is a difficult

thing to do, especially in describing muscle action. The result is that, unless the student already knows the various actions of a muscle, he would be at a loss.

The section on physiology was written for students who may not have had either chemistry or physics and is interesting and informative. The application of physiology in the use of physical therapy modalities is stressed.

The illustrations are excellent and generously supplied throughout. While it may not be desirable as a text, this work does contain valuable material as a reference book for physical and occupational therapists.

CLARA M. ARRINGTON

Genetics, Medicine, and Man—
By J. H. Muller, C. C. Little, and Lawrence H. Snyder. Ithaca, N. Y.: Cornell University Press, 1947. 158 pp. Price, \$2.25.

For most public health workers genetics is one of the little known, minor biological sciences. Until very recently medical and public health curricula were satisfied with brief mention of hemophilia, common in European royal families, and albinism. Most reported hereditary conditions were too rare to justify more than passing reference. Discovery of the Rh factor and its far-reaching importance in maternal and infant health, has re-awakened public health interest in the subject of heredity.

Genetics, Medicine, and Man provides a stimulating review by three eminent specialists. Originally presented as the Cornell Messenger lectures, the informal lecture style adds to the readability of the material.

Dr. Muller summarizes the fundamentals in non-technical language. Equally important for the general reader, he describes the work of the genes in differentiation. Those of us who recall classroom description of mitosis and meiosis in purely mechanical

terms will particularly enjoy Dr. Muller's enlightenment on the dynamics of these processes.

Readers will find Dr. Little's chapters provocative in a different way. His chapters on Parental Influence and on Growth and Individuality highlight a dozen fields in which active research is under way.

Dr. Snyder presents a dependable yet brief summary of human heredity. Specific information on a variety of conditions is included.

MORTON D. SCHWEITZER

State Central Case Record Systems and Local Case Registers for Tuberculosis—
By U. S. Public Health Service, Washington, D. C.: Federal Security Agency, 1947. 88 pp.

This manual describes clearly, simply, and completely how tuberculosis case registers should be planned, installed, and maintained technically. Eight of the ten chapters are devoted to description and discussion of central state tuberculosis case registers (termed "State Central Record Systems"). The other two chapters deal with local case registers.

The manual contains a tentative recommendation that the installation of state case registers be considered in states with populations under four million. Such state registers would contain a summary of current important information for every known case or suspect in the state who is under medical supervision or in need of it. The information would be obtained from various types of reports routed to the central state health agency, including case reports, clinic examination reports, hospital admission, and discharge reports, public health nursing reports, reports from private physicians, laboratory reports, and others.

Such current case summaries would provide sources of knowledge about tuberculosis in the state which would

obviously be of immense value in evaluating, planning, and administering the state tuberculosis control program. However, whether or not a state record system of the *detailed* type recommended would be practicable in so many states is a question which can be settled only after longer experience with it in more states.

The manual emphasizes that the installation of a state record system is a desirable prerequisite to the establishment of local registers in most states. But it recognizes that "the development of a State Central Record System before the existence of local registers leads to many difficulties, the foremost of which is that, in the beginning, the state system must contain more elaborate information than would be necessary if local registers were in operation. Once local registers are developed, the state can make the transition from complexity to simplicity with little effort."

The purposes and methods of use of a state record system are discussed fully. But insufficient attention is given to the methods of using a local case register for its primary purpose of assisting the local health department in the public health supervision and management of individual cases. There is a lack of sufficient emphasis on the fundamental point that the routine clerical maintenance of a register must be supplemented by active professional interest, interpretation, and use by the health officer, the tuberculosis administrator, and the public health nurse.

The clerical procedures recommended are admirably presented in orderly detail. The format is excellent and unique. The inclusion of specimen report forms and statistical tabulation forms adds greatly to the technical value and usefulness of the manual.

EDWARD X. MIKOL

The Ranks of Death: A Medical History of the Conquest of America

—By Colonel P. M. Ashburn. New York: Coward-McCann, 1947. 298 pp. Price, \$5.00.

The late Colonel P. M. Ashburn, at one time librarian of the Surgeon General's Library, has here described and interpreted the medical history of early American settlement. His son, Frank D. Ashburn, has added introductory observations. The book does not provide a historical narrative of the usual sort, since it is arranged primarily in terms of diseases rather than in time sequence. This makes it seem disjointed to the historian, but will appeal to medical men interested in the historic role of particular forms of illness. Spanish-American and English sources are carefully assembled and analyzed.

The following conclusions are presented: (1) that the Indians suffered most from the exchange of European, African, and American diseases; (2) that resulting Indian mortality greatly facilitated the conquest; but that (3) whites and Negroes later suffered much from infections they themselves had introduced. These theses are not novel, but are presented in a convincing manner. The author also discusses disease origins, and adds the sound observation that much illness subsequently ascribed to infections was really starvation or scurvy.

One may question conclusions at a few points; e.g., that it was primarily Negroes who conveyed malaria—which hardly accounts for its wide distribution in colonial New England. The reviewer agrees with the author that historians have usually overlooked the great significance of the disease factor in the conquest. Since Colonel Jones wrote a decade ago, however, a number of careful studies have appeared, such as those of Childs and Ackerknecht on malaria. The bibliography appended is helpful, but does not seem to come down beyond about 1936.

RICHARD HARRISON SHRYOCK

Insect Pests—By William Clunie Harvey and Harry Hill. (2nd ed.) London: H. K. Lewis & Co., Ltd., 1947. Price, 14s net.

The second edition of this English text on insect control has been enlarged by the addition of two new chapters, No. V on "Mosquitoes and Moths," and No. X on "DDT."

The first six chapters on the characteristics and habits of the more important insect pests are generally well written. An occasional confusion in species identification may be noticed, for example, on page 79, where the obsolete term *Stegomyia calopus* is used as if it were a different species from *Aedes aegypti*.

The new chapter on mosquitoes and moths suffers from an apparent lack of acquaintance with newer methods of control, particularly naturalistic methods of value in the control of disease vectors in tropical areas.

Chapter VII on Building Construction and Infestation is particularly well done in concise form. In other chapters too much detail is presented regarding control methods now rendered practically obsolete by newer insecticides and techniques.

The general presentation of DDT in Chapter X is good, but apparently much recent American military and civilian experiment and experience was not available to the authors.

Much of the arrangement of the material is excellent, particularly the presentation of advantages and disadvantages of various materials and methods. The illustrations, however, are frequently disappointing.

The book is apparently written for conditions in the British Isles, and will be of only limited value in American and tropical areas. HAROLD F. GRAY

A Symposium on the Effects of Soil Elements on Food—By T. J. Brooks. Tallahassee, Fla.: State De-

partment of Agriculture, 1947, 175 pp.

The "Symposium" is a motley collection of popular articles and scientific papers on various phases of the "Effects of Soil Elements on Foods" reprinted from publications as diverse as the *Saturday Evening Post*, the *Florida Times Union*, *Miscellaneous Publication No. 536* of the U. S. Department of Agriculture, *Archives of Biochemistry*, and *Southern Medicine and Surgery*, prefaced by four very short chapters by the "author," T. J. Brooks, Assistant Commissioner of Agriculture of the State of Florida. Approximately one-fourth of the reprinted articles are concerned primarily with deficiencies in the soils of Florida; the remainder are chiefly reviews of our present knowledge of the role of minor elements in plant and animal nutrition and the relationship between soil composition and the health of the plants and animals grown on it. This collection of reprinted articles will be of considerable interest to many public health workers who desire to broaden their knowledge of the importance of the minor elements in plant and animal nutrition and the role of soil composition in the production of crops and animals.

DONALD K. TRESSLER

Text Book of Microbiology—By Kenneth L. Burdon, Ph.D. (3rd ed.) New York: Macmillan, 1947, 728 pp. Price \$3.50.

The 3rd edition of this book has been thoroughly revised, and presents a good general survey of the field of bacteriology intended for beginning students.

The book is divided into four parts: Part One, Elements of Microbiology; Part Two, Methods of Destroying Microorganisms and of Controlling the Spread of Communicable Disease—Sources and Modes of Infection; Part Three, Infection and Resistance; and Part Four, Microbiology of Important Infectious Diseases.

The author states: "The purpose has been, as before, to write a clear, balanced account, which is comprehensive and scientifically sound, yet easily understandable, and of real usefulness to student nurses and others interested in the medical and public health aspects of microbiology." As a whole this has been accomplished and it can be recommended to those interested in the general survey of bacteriology.

CHARLES A. HUNTER

Medical Addenda: Related Essays on Medicine and the Changing Order—*New York: The Commonwealth Fund, 1947. 156 pp. Price, \$1.75.*

Those who are familiar with the studies of the New York Academy of Medicine, Committee on Medicine and the Changing Order will find in these five essays a maturation of this committee's broad and timely objectives.

The theme of the first essay by Dr. James Alexander Miller is well epitomized in its final sentence, "In any program for the improvement of medical care the master key to the situation is in the hands of the doctor himself." This and the second essay on Psychosomatic Medicine by Dr. Louis Hamman should be required reading for those who guide the educational destiny of young physicians.

The strong and growing collaboration between medicine and social work is clearly presented in the next two essays, for the medical social worker by Mary Antoinette Cannon and Harriett M. Bartlett, and for the psychiatric social worker by Winifred W. Arrington.

Three phases of medical practice too long neglected and recently emerging into our consciousness are discussed in the final two essays. Dr. Howard Rusk describes the subjects of rehabilitation and convalescence from his intimate wartime and subsequent post-war experience in physical medicine. Dr. Ernst Boas presents an authoritative and well

documented discussion of medical and social problems peculiar to chronic disease. Medically, he stresses the importance of prevention and the need for expansion of present facilities for chronic disease treatment. He believes that the social and economic problems in this field must be attacked by some form of disability insurance and by community planning for more than custodial care and for rehabilitation.

CHARLES E. SHEPARD

Statistical Analysis in Biology—*By K. Mather. (2nd ed.) New York: Interscience, 1947. 267 pp. Price, \$5.00.*

Dr. Mather, as a biologist and non-mathematician, appreciated "the necessity for a better understanding of the potentialities of statistics amongst experimentalists" and has discussed and utilized various methods with sample analyses from the field of genetics. The text includes tests of significance, degrees of freedom and the analysis of variance with the principles of partition, linear, polynomial and multiple regression, inter-class, partial and intra-class correlation, the analysis of frequency data including partitioning chi square, estimation and angular and probit transformations. The steps in the analyses are carefully explained and the examples are clear. Although the public health statistician only rarely uses these methods, he should be cognizant of the advancement of such statistical methods and the practical uses in specialized fields.

RUTH R. PUFFER

The Sanitary Inspector's Handbook —*By Henry H. Clay, F.R., San.I., F.I.S.E.; Major, R.A.M.C.; with an introduction by Sir Wilson Jameson, M.A., M.D., F.R.C.P., D.P.H. (6th ed.) London: H. K. Lewis & Co., Ltd., 1947. 545 pp. Price, 22s.*

This is the sixth and revised edition of a book originally published in 1933.

It is designed to assist sanitary inspectors of England, Scotland and Wales in solving their technical and legal problems, and to serve as a text for candidates for certification as "sanitary inspectors" by the Royal Sanitary Institute and Sanitary Inspectors Examination Joint Board.

The author considers only British laws, regulations and practices. For that reason, American readers will find much of the book not applicable to this continent. No doubt many American

public health officials will regret that there is not available a similar text for their particular health jurisdictions. Major Clay's book should be of great value to any American reader who might contemplate the preparation of a compilation of sanitation laws, regulations and methods for a specific health jurisdiction. It should also be of interest to anyone who wishes to compare British and American public health administration and practice.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

When Johnny Comes Marching Home—We tend to think of our recent increase in birth rates as phenomenal, but some of the other countries make our 1946 rate of 23 appear to be something less than colossal. Canada's rate was 26, South Africa's (White) 27, and the Netherlands 30—not to mention Venezuela's 38 and Mexico's 42.

ANON. World-Wide Resurgence in Birth Rates. Statistical Bull. (Met. Life Ins. Co.) 28, 9:1 (Sept.), 1947.

Gourmets in the Making—Don't call it "self-demand." Instead, say "self-regulation" while assessing the virtues of feeding babies when they tell you they are hungry. Less than 1 per cent of the tikes who were allowed to

choose their meal times failed to do as well as most clock-fed infants.

ALDRICH, C. E. and HEWITT, E. S. A Self-Regulating Feeding Program for Infants. J.A.M.A. 135, 6:340 (Oct. 11), 1947.

How's Your Vocabulary?—If you can rattle off a concise and exact definition of every word in the title of this paper, then it is possible that you will not need to review it. But if some of the words stump you, then you may add a little to your tiny store of understanding—providing you have a dictionary handy—by reading it. Any comment here on the whole paper would be as hopelessly inadequate as it would be presumptuous.

AYCOCK, W. L. and CURLEY, F. J. Variolation as a Principle: Immunization in Experimental Poliomyelitis with Active Virus Under Autarceologic Protection of Estrogenic Substance. Am. J. M. Sci. 214, 2:128 (Aug.), 1947.

Hope of the World—Though the human race is threatened as never before, science—given sufficient freedom—can be of real use in charting the world's course. So asserts the Executive Secretary of WHO.

CHISHOLM, B. On the March for Mental Health. Survey Graphic 36, 10:509 (Oct.), 1947.

Department of Applied Humility—Probably the greatest benefit you will derive from reading this paper will be a wholesome appreciation of what we have still to learn about the science of nutrition. You will “lay down the law” about family dietetics a little less *ipse dixit*-edly if you will expose your mind to this review article.

ELVEHJEM, C. A. and KREHL, W. H. Imbalance and Dietary Interrelationships in Nutrition. J.A.M.A. 135, 5:279 (Oct. 4), 1947.

Second Thought Division—Do you remember, in the December, 1946, bibliography, an annotation on a study of the possible direct relationship be-

tween caries and poliomyelitis? Polio patients were said to have twice as many carious teeth (with pulp exposed) as did “comparable” controls. The comparability of the controls has since been questioned. Now comes a new study reporting the finding that the incidence of exposed pulp was essentially the same in polio patients as it was in their siblings who had escaped the disease.

FINN, S., *et al.* Exposed Dental Pulp as a Portal of Entry for the Virus of Poliomyelitis. Am. J. Hyg. 46, 2:177 (Sept.), 1947.

This Is About Garbage—If you have not already heard, you will probably hear, some alarm-viewer air his worries about the overloading of municipal sewage works by the growing use of household garbage grinders. In Washington, D. C., the city is planning to begin grinding large quantities of refuse. They figure that when all garbage is ground the sewage disposal plant can readily be increased to accommodate the added load and that it will cost about 8 cents per capita to dispose of domestic garbage in that way.

FUHRMAN, R. E. Garbage Grinding Planned for the District of Columbia. Sewage Works Engin. 18, 10:518 (Oct.), 1947.

Top Notch—In so far as the viruses are concerned it is not enough that circulating antibodies exist. To be effective the antibodies must be sufficient in power and in the right place and there at the right time to block invasion, says this researcher. This excellent paper discusses four groups of viruses. It is not an easy one to read but you really should try to assimilate it.

FRANCIS, T. Mechanisms of Infection and Immunity in Virus Diseases of Man. Bact. Reviews 2, 3:147 (Sept.), 1947.

Forty Per cent Savings—Four topical applications of 2 per cent sodium fluoride, preceded by dental prophylaxis are the minimum number needed to give maximum protection.

GALAGAN, D. J. and KNUTSON, J. W. The Effect of Topically Applied Fluorides on Dental Caries Experience. *Pub. Health Rep.* 62, 41:1477 (Oct. 10), 1947.

Treat Instead of Treatment—After two decades of thumbing the same old journals and skimming the same old subjects—served up usually in the same old plodding style—a mental astigmatism tends to set in. Then, suddenly appears something inspired, something to make this ancient skimmer see clear and straight again. Though said skimmer is not sufficiently the psychologist to be able to assure you that every pronouncement is “sterling” grade, he promises you that every paragraph is a treat.

MACKAY, R. P. The Neurologist Looks at Discipline. *J.A.M.A.* 135, 7:399 (Oct. 18), 1947.

Paradox—It may be, concludes this writer, that we have increased the incidence of poliomyelitis disease while cutting down the rate of infection through better hygiene and sanitation by moving the age of infection into the older age group.

NELSON, N. Susceptibility and Immunity in Poliomyelitis. *J. Immunol.* 56, 4:311 (Aug.), 1947.

This You Should Know—Here is a good, easy-to-grasp statement on the status of streptomycin in the treatment of tuberculosis. Streptomycin is a valuable adjuvant, with a suppressive effect. Because not all lesions are curable, and because of the toxicity of the drug it should not be used indiscriminately. Neither is it a substitute for bed rest and related treatment measures.

PYLE, M. M., *et al.* Streptomycin in the Treatment of Tuberculosis. *Pub. Health Nurs.* 39, 10:498 (Oct.), 1947.

Q Fever—An outbreak of Q fever occurred among packing house workers

whose gory jobs exposed them to spattered blood. There were no infections among the men who handled the sheep and calves before they were slaughtered, and ticks seemed to have played no part.

SHEPARD, C. C. An Outbreak of Q Fever in a Chicago Packing House. *Am. J. Hyg.* 46, 2:185 (Sept.), 1947.

Three Pictures to Turn Your Stomach—You will be cheered a little by this brief account of what some practical humanitarians propose to do about bettering the hideously insanitary folkways of China where open sewers still disfigure the main streets of great cities.

SNELL, J. R. Sewage Disposal in China a Major Problem for the Future. *Sewage Works Engin.* 18, 10:526 (Oct.), 1947.

It Pays to Try Everything—If fruit flies could carry polio virus, they might easily account for the spread of disease. That is clear, isn't it? Well, a beautifully controlled study was carried out. It indicated that fruit flies can be grossly contaminated with virus, but under any condition which might be duplicated in nature, the flies were unable to transfer the infection. So the answer is: fruit flies are of no epidemiologic importance.

TOOMEY, J. A., *et al.* Can *Drosophila* Flies Carry Poliomyelitis Virus? *J. Infect. Dis.* 81, 2:135 (Sept.-Oct.), 1947.

Turning Point—A year after Koch described the tubercle bacillus, experimenters began the attack on the disease with non-pathogenic competitors. Now, sixty-odd years later, we seem to be getting somewhere. This review of the long drawn and often disheartening battle, coming from the pen of the man who gave us streptomycin, is something you'll not want to miss.

WAKSMAN, S. A. Antibiotics and Tuberculosis. *J.A.M.A.* 135, 8:478 (Oct. 25), 1947.

Standing, left to right: Dr. Oswald T. Avery, Dr. Lowell J. Reed, Dr. Thomas Francis, Jr., Dr. Homer Smith, Dr. Thomas Parran, Sir Wilson Jameson, Dr. George Baeher, and Dr. Reginald M. Atwater. Seated: Mrs. Albert D. Lasker and Dr. Alice Hamilton.

THE LASKER AWARDS FOR 1947

THE Lasker Awards of the American Public Health Association are presented annually by the Albert and Mary Lasker Foundation to men and women in the field of medical research and public health administration whose efforts have contributed to, or will in time result in, the vastly improved health status of the peoples of the earth. In addition, outstanding work or research done by large groups where it is impossible to single out any one individual, is honored.

The awards are given not only to honor the recipients and dramatize their accomplishments but also to arouse increased professional and public interest in medical research and public health administration and to aid in the rapid

dissemination of new medical information.

The Lasker Awards for 1947 were conferred on October 9, 1947, at the Second General Session of the 75th Annual Meeting in Atlantic City, N. J. Five individuals and two groups were honored. The beautifully illuminated citations read as follows:

To Oswald T. Avery, M.D., for studies on the antigenic constitution of bacteria.

With unusual persistence, remarkable insight and extraordinary accuracy of observation, Oswald T. Avery has devoted the greater part of his scientific career to the study of the pneumococcus.

Animated by an unsurpassed intellectual curiosity and a desire to conquer one of the most deadly enemies of man, he undertook to elucidate in logical sequence the biological

activities, the immunological characteristics, and the pathogenic properties of the pneumococcus. In this he so far succeeded that today it is fair to say that more is known about this organism than about any other human parasite.

Were this all it would be a unique accomplishment, but quite early in the course of his investigations he became interested in searching for a chemical explanation for the type-specificity of pneumococci. As a consequence, he discovered and identified the capsular polysaccharides and demonstrated their role in determining this specificity.

He furthermore succeeded in throwing light on the immunological relationships of the intracellular constituents of this organism.

Through these discoveries he laid the foundation for his brilliant analysis in chemical terms of the antigenic constitution of the whole pneumococcus. He thus established a perfect pattern for the antigenic analysis of other microorganisms both by himself and by others who have followed in his footsteps.

Among Dr. Avery's many brilliant contributions to scientific knowledge none has been more outstanding than his studies on the antigenic constitution of bacteria. Through them he is one of the founders of the science of immunochemistry. Because of them our comprehension of the complex problems of infectious disease has been immeasurably enriched.

To Thomas Francis, Jr., M.D., for distinguished services through contributions to our total knowledge of influenza.

Thomas Francis, Jr., is honored with The Lasker Award in recognition of his distinguished contribution to our knowledge of influenza, and his effective leadership in the world-wide fight against this scourge of mankind.

Dr. Francis's researches on influenza began about two decades ago. In 1928 he joined the staff of the hospital of the Rockefeller Institute, and in 1936 he organized for the International Health Division of the Rockefeller Foundation the influenza study laboratories where pioneer work was done on the etiology and epidemiology of the disease. In 1938 he became Professor of Bacteriology at New York University, and in 1941 he accepted the professorship of Epidemiology and Chairmanship of the Department of Epidemiology in the newly established School of Public Health in the University of Michigan. In 1947 Dr. Francis was appointed to a distinguished professorship at Michigan, known

as the Henry Sewell Professorship of Epidemiology.

Dr. Francis's contributions to scientific literature have been numerous and have brought him many honors. Since the first report in 1934 on the recovery of the virus of influenza A in the Western Hemisphere, which confirmed the primary observation of Smith, Andrewes, and Laidlaw, Dr. Francis's studies have included a series of immunological, epidemiological, and clinical observations directed toward a better understanding of the human disease. The demonstration with Magill of serological variations in strains has resulted in sustained studies of its significance in recurrent epidemics. The identification of influenza B and isolation of that virus added clarification to the problem by establishing a new entity in a complex field. His continuous investigations have contributed much to our knowledge of the global aspects of the disease.

Studies of the selective action of influenza virus on the respiratory epithelium and of antibodies in the respiratory secretions have given insight into the mechanisms of infection and immunity. From the original demonstration in 1936 that influenza virus given subcutaneously or intradermally could induce the formation of antibodies in man, successive studies have brought evidence in controlled observations of the effectiveness of human immunization against influenza.

As Director of the Commission on Influenza of the Army Epidemiological Board, Dr. Francis organized and actively participated in the establishment of "listening posts" for the detection of influenza in various parts of the United States, and in the Army studies which gave evidence that vaccination can be effective against epidemic influenza A and influenza B.

Thus Dr. Francis, through his own contributions and through his stimulation of other investigators, has made a notable contribution to our knowledge of influenza which affords a sound foundation for future work, and has created the hope that this disease may be eventually conquered.

To Homer Smith, D.Sc., for distinguished services through conclusive studies on cardiovascular and renal physiology.

Homer Smith is honored for his distinguished contributions in the fields of renal and vascular physiology.

His work falls into a unique and logical pattern. Early fundamental studies upon osmotic regulation in fish provided a basis for

a masterly analysis of the available data in the formulation of a theory of the evolution of the mammalian kidney.

Within this frame, he has been led to a fruitful investigation of the specific activities by which the mammalian kidney performs its regulatory duties. Unalterably opposed to the "unphysiological preparation" in experimentation, he devised simple tests by which glomerular filtration rate, renal blood flow, and renal tubular capacities might be measured quantitatively without pain, operative procedures, or anesthesia.

These tools of investigation are applicable in the study of man, and under Dr. Smith's direction, they have been energetically employed in man in clarifying problems of renal function in health and disease.

These studies are masterpieces of clinical investigation, sparkling with new concepts, gracefully phrased and logically developed. They have thrown new light upon the problems of renal and cardiorenal diseases, which are at present the chief causes of death, and have provided the background for many future investigations in this important field of medicine and public health.

Homer Smith has also been prominent among those responsible for the physiological bearing of the current trend in medical thinking. In part this influence springs from the character of the man.

Modest, self-effacing, and consecrated to his work, he does not shun the fight for what he considers is right, fair, and just. In paying tribute to his work, we pay homage to the man.

To Alice Hamilton, M.D., for an inspiring life of public service in the prevention of occupational disease.

To Dr. Alice Hamilton, pioneer American leader in industrial toxicology, for her contribution to the development of public health methods in industry, and to the prevention of occupational diseases.

After graduating in medicine at the University of Michigan in 1893, and postgraduate studies in Germany, Dr. Hamilton returned to the United States intending to specialize in bacteriology, pharmacology, and toxicology.

Because of her growing interest in social progress and labor reform, which increased through her friendship with Jane Addams and her associates at Hull House, Dr. Hamilton began to specialize in industrial medical problems shortly after the turn of the century. At that time industrial medicine was not yet considered a specialty, and the need for

physicians in industry was not generally recognized.

Through her efforts to prevent lead poisoning, "phossy jaw" in the match industry, mercury poisoning, TNT poisoning in World War I, and her later investigations of benzol, carbon disulfide and other organic solvents, she has contributed much to the control of these hazards and to the establishment of the profession of industrial preventive medicine in this country.

Throughout her useful life Dr. Hamilton has worked to improve the health of human beings. She has helped the laborer, the unions, the large manufacturers, the universities, and the government, and all her investigations have been carried out with complete objectivity and fearless candor. She has never been either pro labor or pro capital, but has stood unwaveringly for the betterment of the worker's health.

Dr. Hamilton has been associated with many educational institutions, and the excellence of her contributions has been widely recognized by her scientific associates. After 26 years of service, she is now retired as one of the Emeritus Professors of the Harvard School of Public Health.

This Lasker Award is given to Dr. Hamilton in recognition of her outstanding accomplishments in industrial toxicology, and for the inspiration she has afforded to all those who are interested in industrial preventive medicine and world health.

To Thomas Parran, M.D., for outstanding contributions to the national health and to the World Health Organization.

Dr. Thomas Parran has achieved worldwide acclaim for his dynamic leadership in public health administration as well as for his successful pioneering against preventable disease. He is also the great advocate of support for medical research before the Congress and the American people.

Dr. Parran's public health service career has been a succession of striking achievements. It began during World War I with responsibility for extra-cantonment sanitation in an industrial city and its environs. He then organized county health work in the rural areas of several states, headed a sanitary district in a mining area, served as chief of rural sanitation activities in another state. He was Assistant Surgeon General of the U. S. Public Health Service in charge of the Division of Venereal Disease in its early days.

In 1930, he was loaned by President Hoover to Governor Roosevelt to become Commis-

sioner of Health of the State of New York, where he served with distinction for six years. For the past eleven years, he has served as Surgeon General of the U. S. Public Health Service.

In 1946, he was president of the International Health Conference of delegates from seventy nations, which resulted in the establishment of the World Health Organization of the United Nations. Since then, he has been the United States Delegate to the Interim Commission of the World Health Organization.

Throughout his brilliant public health career, Dr. Parran's activities have been significantly characterized by the qualities of judgment, enthusiasm, courage, decisiveness, and vision.

This has been especially true of his forthright approach to the control of the venereal diseases, which began with the breakdown of public prejudice against the use of the terms "syphilis" and "gonorrhea."

This was followed by successive steps leading to the appropriation of federal grants-in-aid to the states, and the eventual establishment of rapid treatment centers throughout the land. If syphilis is finally wiped out in this country, it will be due to Dr. Parran's consistent courage and statesmanship, as much as to the discovery of a curative drug.

With a vigorous originality of approach, he has developed new concepts of health services for the American people and the world. In addition, he has been able to secure the understanding and interest of the people and the support of their elected representatives. He has contributed substantially to the development of the World Health Organization, important both because of its life-saving mission and because it may prove to be a "rallying point of unity" in international affairs.

As Dr. Parran himself recently said in a foreword to a summary of the history of the World Health Organization—"We in the United States must carry on two major jobs at once—we must maintain a place of leadership in world health affairs and at the same time redouble our efforts to attain a more comprehensive health program at home. We are faced with great opportunities for service to humanity."

In recognition of these and other services to the people of America and the world, the Lasker Awards Committee of the American Public Health Association has recommended that a Special Award be made this year to Dr. Parran, which will express the appreciation of this Association for his inspiring public

health leadership in domestic and world affairs.

To the British Ministries of Food and Health, for the unprecedented program of food distribution in Great Britain, with resulting improvement in the health of the people.

Long before World War II, the Medical Research Council and the health authorities of Great Britain had been active in promoting research and in spreading knowledge of nutrition among the people.

In 1937 an Advisory Committee on Nutrition was set up by the British Ministry of Health which undertook a survey of the national diet. The background had therefore been developed before the outbreak of the war for the first large-scale application of the science of nutrition to the population of the United Kingdom. A separate Ministry of Food was established with wide executive powers over the production and rationing of foods, the purchase of foods from abroad, and the education of the public in the proper use of available foods. By the effective employment of its great powers, the Ministry of Food, in consultation with the Ministry of Health and with the advice (on all matters which might affect the health of the people) of a Standing Committee under the chairmanship of the Chief Medical Officer, succeeded to a remarkable degree in providing a diet for all the workers of the country in conformity with their physiological requirement, irrespective of income.

Although almost all other environmental factors which might influence the public health deteriorated under the stress of war, the public health in Great Britain was maintained and in many respects improved. The rates of infantile, neonatal and maternal mortality and of stillbirths all reached the lowest levels in the history of the country. The incidence of anemia and dental caries declined, the rate of growth of school children improved, progress was made in the control of tuberculosis, and the general state of nutrition of the population as a whole was up to or an improvement upon pre-war standards.

In the opinion of the Lasker Awards Committee, this has been one of the greatest demonstrations in public health administration that the world has ever seen. The Lasker Awards Committee of the American Public Health Association therefore takes great satisfaction in recommending awards for scientific and administrative achievement to

the British Ministries of Food and Health and to the four great leaders in this historic enterprise. Lord Woolton, Sir Jack Drummond, Sir Wilson Jameson, and Sir John Boyd Orr.

(Sir Wilson Jameson received the award on behalf of the group.)

To the United States Committee on Joint Causes of Death, for significant contributions to the international classification of diseases, injuries, and causes of death.

The Lasker Award of the American Public Health Association represents the appreciation of the workers in public health and medical care for the scholarly achievement of the United States Committee on Joint Causes of Death under the chairmanship of Dr. Lowell J. Reed. The work of this committee will greatly facilitate the exchange of statistical information on health and medicine between the countries of the world, and serve as one of the effective links in binding them together under the banner of the United Nations.

Although early classification of the causes of death for statistical purposes goes back to the great English medical statistician, William Farr (1855), the first international conference for the revision of the *International List* was called by the French Government in Paris in the year 1900, at which time the guiding force was Dr Jacques Bertillon. There was early recognition of the need for an international list of the causes of illness to facilitate the collection and exchange of information by all the countries of the world, supplementing the causes of mortality.

At the Fifth International Conference held in Paris in 1938 to revise the *International List*, the United States Government was requested officially to continue the previous studies of the Committee on Joint Causes of Death and to extend it into the field of morbidity classification. In 1945 the Secretary of State appointed the United States Committee on Joint Causes of Death to carry out this charge. The committee included representatives of the Canadian and British Governments and the Health Section of the League of Nations as associates or consultants and was headed by Dr. Reed, Vice-President and Professor of Biostatistics at the Johns Hopkins University.

Under Dr. Reed's inspired leadership and with the coöperation of its British and Canadian associates the committee accomplished its task successfully. A preliminary draft of the proposed statistical classification of diseases, injuries, and causes of death was then subjected to trials and reviews of various agencies and individuals in England, in the United States, and in Canada. The United States Committee met in Ottawa in March, 1947, with the International Committee which has been appointed to prepare for the 6th decennial revision of the *International List of Causes of Death*, and at this time the work of the United States Committee was adopted by the International Committee as the basis for its recommendations to the nations of the world when their representatives reconvene in Paris in 1948 for the purpose of revising the *International List*.

(Dr. Lowell J. Reed received the award on behalf of the group.)

ASSOCIATION NEWS

Martha M. Eliot, M.D., President of American Public Health Association

Dr. Eliot, a native of Dorchester, Mass., was graduated from Radcliffe College, Cambridge, Mass., in 1913, and received her M.D. degree from Johns Hopkins University in 1918. After an internship at the Peter Bent Brigham Hospital in Boston, Dr. Eliot served a pediatric residency at the St. Louis Children's Hospital and worked in the same field at the Massachusetts General and the New Haven Hospitals. She became identified with the Department of Pediatrics at Yale in 1921, advancing to the rank of Associate Clinical Professor and Attending Pediatrician of the New Haven Hospital and New Haven Dispensary.

Best known because of her relationships with the U. S. Children's Bureau, Dr. Eliot served as Director of the Division of Child and Maternal Health, 1924-1934, and was Assistant Chief of the Children's Bureau 1934-1941. Since May, 1941, she has been Associate Chief. Most recently Dr. Eliot on loan from the Children's Bureau has served as Chief Medical Consultant of the International Children's Emergency Fund of the United Nations, during which service she has made several trips to Western and Central Europe.

Dr. Eliot's professional connections include Fellowship in the American Public Health Association, in the American Medical Association, membership

in the American Academy of Pediatrics, in the American Institute of Nutrition, and in the American Pediatrics Society. She also is identified with the Society

Martha M. Eliot, M.D.

for Research in Child Development and has published widely in the field of nutrition and especially of rickets. She was inducted into the Presidency of the Association on October 10, 1947, at the close of the 75th Annual Meeting, and carries the honor of being the first woman elected to this office.

Sedgwick Memorial Medal for 1947 Awarded to Dr. Atwater

THE award of the Sedgwick Memorial Medal of 1947 was made on November 7 during the Seventy-fifth Annual

Meeting in Atlantic City, N. J., to Reginald M. Atwater, M.D., Executive Secretary of the Association. It was

presented by the Chairman of the Sedgwick Memorial Medal Committee, Brigadier General James Stevens Simmons, U.S.A. (Retired), Dean of Harvard School of Public Health. The citation follows:

The award of the Sedgwick Memorial Medal is the highest honor which can be conferred by this Association. This medal has been awarded to distinguished investigators in the field of laboratory science, to epidemiologists, to college professors, to the administrative officers of national and local health services.

The man selected to receive this award for 1947 could qualify on two of these grounds. He has been a teacher at the Hunan-Yale College of Medicine in Changsha, and at the Harvard School of Public Health. He was a health officer for eight years and directed the notable health demonstration at Cattaugus County, N. Y. In particular, however, we honor him today for the "Distinguished Service in Public Health" which he has rendered as Executive Secretary of the American Public Health Association.

We need executive leadership of the finest type in our local and state and federal health departments, and in the voluntary agencies which must play an increasingly important rôle in our program of total war against disease. We need it also in the American Public Health Association itself, the one organization which represents the public health profession as a whole and has done so much to develop and to integrate its program. We celebrate this year the Seventy-fifth birthday of the Association. We review with pride the vision of Stephen Smith and his associates who founded this organization in 1872. We rejoice in the fact that this is no narrow national body; Canada, Cuba, and Mexico are equal members with the United States. Our Association represents the whole North American Continent. We are proud of its

11,000 members, its admirably planned meetings, and its JOURNAL. We recall with satisfaction the accomplishments of its major standing committees; the Committee on Research and Standards, which is responsible for our authoritative reports on standard methods; the Committee on Administrative Practice, which has provided sound objective methods of evaluating health department procedures and a concrete plan for developing local health units; and the Committee on Professional Education, which has furnished wise leadership in stimulating training and furthering the sound selection of professional personnel.

No one could be more pleased than William T. Sedgwick, if he could observe the progress of the Association along these lines. He was a moving force in the creation of the Laboratory Section as the first specialized Section of the Association nearly half a century ago. He was a loyal and an ardent member, and encouraged his students to join the American Public Health Association and to serve it with similar devotion. I know that I speak for him when I present the Sedgwick Medal to Rex Atwater.

The Association has grown in size and in capacity for service more during the last twelve years than in the earlier six decades of its history; and that growth has been largely due to its Executive Secretary.

In this difficult task he has shown wisdom of rare quality in dealing not only with administrative problems but with the broad policies of a profession which is today inevitably entering new and controversial fields. His wisdom has been inspired by unflinching courage which has faced decisions without any fear of personal consequences. His firmness in matters of principle has been tempered by unfa'ling patience and by an essential humanity which has earned not only our respect but our personal affection. He has served the cause of

public health with complete devotion and with a modesty that has often hidden the crucial part he has played in forming the program and policies of the organization.

This modesty led him to protest the unanimous decision of the Sedgwick Award Committee and to say that he felt that the Medal should not be given to an executive officer of the American Public Health Association. He remarked that such executives were only doing their duty.

This same modesty, SIR, will no doubt cause you to say that the Sedgwick Award for 1947 is an award to the American Public Health Association as well as to yourself. That is, in a measure, true; but it has been well said that great events are the shadows of great men. In the name of William T. Sedgwick and of the American Public Health Association I hand to you, Dr. Atwater, the Sedgwick Memorial Medal "FOR DISTINGUISHED SERVICE IN PUBLIC HEALTH."

In accepting the award, Dr. Atwater responded as follows:

This is a highly appreciated honor, General Simmons, which you and the Committee have conferred upon me. I prize it as a recognition that the operation of our professional society is an important factor in the progress of public health. It thus has a part along with research and teaching and public administration where all the previous recipients have been engaged.

The American Public Health Association is indeed a wonderful fellowship to which I owe much as a result of these years of close identity. I am grateful for the privilege of serving for a period which represents just one-sixth of the time since the founding of the Association. It has indeed been a priceless opportunity to know the giants in our field of service.

After all, as Winslow has so well said,

the purpose of this award is not primarily to place each year a crown on the brow of a more or less worthy recipient. The purpose is to keep the laurel green on the memory of a great pioneer in American public health. William Thompson Sedgwick was a human being whose personality, whose soul, was far more significant than any or all of his concrete achievements.

It is altogether fitting that the memory of a great teacher should be perpetuated by his colleagues so that succeeding generations may understand something of the spirit and the quality of the man. One of Professor Sedgwick's friends wrote, "There was something cumulative in the good he wrought, so that the sense of his worth came unawares upon one like the approach of morning. Beyond the immediate friendliness of the man lay a constancy and fulness of good will that was impersonal and really great, measurable only as it is withdrawn."

Other recipients of the Sedgwick Medal have recorded the extent of the influence which he had on them as teacher and friend over many years. My own direct contact was condensed into a single lecture which I heard him give to the students of the Harvard-M.I.T. School of Public Health. Yet from that single occasion I retain after 30 years a lively sense of his personality and power and I welcome this opportunity of acknowledging an unpayable debt. The 26 years which have elapsed since the untimely death of Professor Sedgwick have allowed us to appreciate the real stature of a great man. His imprint upon the American Public Health Association may still be readily discerned. He knew the quality of effort that went into the foundations. He must have pleasure in the progress that has been recorded in these years since he left us.

The foundations which Professor Sedgwick built into the Association

were solid and durable. He served the Association long and well, being President in 1915. The contributions which he made to the *American Journal of Public Health* are specially meaningful to me. I am told that for several years, beginning about 1915, every issue of the *Journal* printed was personally underwritten by Professor Sedgwick who guaranteed the bill with the printer. So he not only motivated the *Journal* in its policy and content but he added a very practical support without which publication would have been impossible!

An executive of a professional society who receives such an award will know as I know that any success which he has attained goes back in largest measure to the colleagues among whom he spends his life. It is they who make success

or failure for such a society as this. At best the executive can only create a favorable climate. Behind these staff associates, of course, stand the chairmen and the members of about 100 committees who have faithfully labored that the American Public Health Association might live.

It is proper, therefore, that such an award should be accepted on behalf of these faithful Fellows and members of the Association and also on behalf of a loyal staff without whose patient labors and outstanding teamwork it would all fail. In their name and in recognition of their fine support I am proud to accept this award. I hope that as we deal with students today we may help them to be as useful as Sedgwick's students have been.

RESOLUTIONS

THE following Resolutions were unanimously adopted by the Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 8, 1947:

1. APPRECIATION TO OFFICIALS AND GROUPS

RESOLVED that the American Public Health Association expresses its grateful appreciation to the New Jersey Committee and the agencies represented thereon for their gracious hospitality, and be it further

RESOLVED that the warm thanks of officers and members be extended to Samuel L. Salasin, M.D., General Chairman of the New Jersey Committee and his colleagues on the Committee for their many courtesies and their efficiency in making provisions for this meeting and in the conduct thereof.

2. THANKS TO THE AUDITORIUM AND HOTELS

RESOLVED that the American Public Health Association expresses its ap-

preciation to the Convention Hall and to the Hotel Ambassador for their valuable assistance in the conduct of the Seventy-fifth Annual Meeting.

3. APPRECIATION TO THE PRESS

RESOLVED that the American Public Health Association acknowledges its indebtedness to the press, national, state, and local, for excellent service in connection with the Seventy-fifth Annual Meeting.

4. APPRECIATION TO EXHIBITORS

RESOLVED that the American Public Health Association expresses its grateful appreciation to those who have presented at its Seventy-fifth Annual Meeting the excellent exhibits, both scientific and technical, which are of such great interest and value to the public health profession.

5. IN MEMORIAM

RESOLVED that it is with a sense of irreparable loss that the American Public Health Association records,

since its last Annual Meeting, the death of fifty-seven fellows and members, the names of whom constitute a part of this resolution.

*Deceased Members and Fellows of the American Public Health Association
November, 1946, to October, 1947*

Robert G. Townsend, Lincoln, Nebr.	1946	
James E. Wolfe, M.D., Wichita, Kan.	1942	

6. INTERNATIONAL FOOD EMERGENCY

WHEREAS, the spectre of hunger and disease in widespread areas of Europe stands in the way of orderly progress toward a stable world order; and

WHEREAS, the United States of America is one of the few fortunate nations that can divert substantial quantities of food from livestock feeding, industrial use, and direct consumption without sacrifice to the health of our citizenry; therefore be it

RESOLVED the American Public Health Association pledges its full support to official and voluntary measures to bring relief to the stricken countries of Europe.

9. RESOLUTION ON THE INTERNATIONAL CHILDREN'S EMERGENCY FUND OF THE UNITED NATIONS

WHEREAS, the United Nations, to aid in meeting the emergency situation of child health and welfare in many countries has established the International Children's Emergency Fund as an agency of the United Nations, and

WHEREAS, substantial evidence exists that there is widespread undernutrition and other threats to child health, and that the governments of the countries involved are without adequate means to combat these conditions, and

WHEREAS, the International Children's Emergency Fund has projected programs of child feeding and child health which are properly designed to meet a primary emergency child health problem, and

WHEREAS, the International Children's Emergency Fund is effectively coordinating its work and cooperating in practical ways with the Interim Commission of the World Health Organization, The Food and Agriculture Organization and other United Nations organizations concerned, and is developing the coordination of voluntary effort as well as that of governments, be it

RESOLVED, that the American Public Health Association approves the program of the International Children's Emergency Fund and urges that it receive full and immediate support of the government and people of the United States.

10. PREVENTION OF PREMATUREITY

WHEREAS, prematurity ranks first in the causes of infant mortality and is among the ten leading causes of death in the nation as a whole, be it therefore

RESOLVED that the American Public Health Association respectfully directs the attention of state and municipal authorities to this situation and

recommends appropriations for a program for the prevention of prematurity and for the provision of facilities for the adequate care of premature infants.

11. OLEOMARGARINE

WHEREAS, generally rising prices of essential foods constitutes a serious threat to the nutrition and well-being of the American People, and

WHEREAS, butter and other fats, important dietary essentials, have been in the foreground of these price rises, and

WHEREAS, scientific evidence has shown

that fortified oleomargarine supplies the food factors usually expected of butter, and

WHEREAS, present federal and state taxes on oleomargarine seriously raise the retail price of this commodity, thus violating the principle that government should facilitate rather than hinder the provision of a satisfactory diet for all the people, be it therefore

RESOLVED that the American Public Health Association condemns specific taxes on oleomargarine, and respectfully petitions the Congress and the various State Legislatures to repeal these taxes.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the Sections indicated.

Health Officers Section

Owen F. Agee, M.D., 1828 Audubon St., New Orleans, La., Acting Director, Division of Local Health Service, State Dept. of Health
 Mario Batinga de Araujo Lessa, M.D., Servico Especial de Saude Publica, Caixa Postal 621, Belem, Para, Brazil, S. A., Physician

ACCREDITATION OF TULANE UNIVERSITY

Tulane University School of Medicine, Department of Public Health, has been accredited for the academic year 1947-1948 to give the Master of Public Health degree. On October 6, the Committee on Professional Education voted to recommend to the Executive Board the accreditation of Tulane University. Accreditation was granted by the Execu-

tive Board on October 8, 1947. This brings the number of institutions accredited to give the Master of Public Health (M.P.H.) degree, (Diploma of Public Health—D.P.H.—in Canada) to a total of eleven. Of these institutions seven have been accredited for 1947-1948 to give the Doctor of Public Health (Dr.P.H.) degree.

Master's degree plus 4 years' experience in public health laboratory; or 3 years of experience and one year of study in approved school of public health. Salary \$325-\$400 monthly. Write Box S-2. Employment Service. A.P.H.A.

Supervising Nurse with degree, experienced, for County Health Department with a staff of ten nurses. Salary \$3,120 plus mileage. Write Box T-3. Employment Service. A.P.H.A.

Public Health Nurses (Staff Nurses, Supervisors, Educational Directors, Consultants, Directors). Many interesting positions with good salaries available in voluntary and official agencies in various sections of the country, both urban and rural. At least minimum N.O.P.H.N.

qualifications required for most positions in the different grades. No fees of any kind. To register for placement visit or write to the Nurse Counseling and Placement Office, New York State Employment Service, 119 West 57th Street, New York 19, N. Y.

Apprentice Training Program for Public Health Nutritionist in New York State

The New York State Health Department announces a new program for the training of public health nutritionists. The objective is "to offer experience under close supervision in the public health field to nutritionists with good academic training but inadequate field experience."

A.B.S. degree from a recognized institution with sound training in human nutrition and one year of graduate work leading to a master's degree represents the basic academic requirement. In addition, it is desirable that workers in public health nutrition have special courses in public health education, community organization and resources, child development, and the making of dietary studies.

It is planned to offer a 12 month period of supervised field service on an annual stipend of \$2,500 plus travel allowance. Car desirable but not essential. Write to Senior Nutritionist, Division of Maternal and Child Health, New York State Department of Health, 39 Columbia Street, Albany 7, N. Y.

POSITIONS WANTED

Non-medical administrator, male, age 33, trained and experienced in community organization, program development, rehabilitation, publicity, public relations; at present employed in large state welfare planning and action organization. Interested in position as executive secretary or in related function in voluntary or official health agency. Write Box A-529. Employment Service. A.P.H.A.

Staff Public Health Nurse for generalized program at the Mamaroneck Health Center, Inc. Salary \$2,580 per year. Thirty-eight hour work week—car furnished. Apply to Mrs. Genevieve Heatley, President, Mamaroneck Health Center, Inc., 234 Stanley Avenue, Mamaroneck, N. Y.

Dental Hygienists for Child Health Programs. Beginning Salaries \$2,168.28-\$2,394. Write to: U. S. Public Health Service, Dental Public Health Section, Washington 11, D. C.

Tuberculosis Clinician. Duties include organizing and supervising tuberculosis diagnostic clinics throughout the state, organizing community and industrial x-ray surveys, interpreting x-ray films, and assisting with other related tuberculosis control activities. Must be elig-

ible for West Virginia license. Salary range, \$420 to \$500 monthly, plus travel. Address inquiries to West Virginia State Dept. of Health, Charleston, W. Va.

Supervisor of Health Education Department needed in Chicago and Cook County Tuberculosis Institute, man preferred. Candidates must have public health background and experience in community education programs. Salary open. Excellent opportunity for developing broad education in tuberculosis control programs. For further information write Dr. E. E. Kleinschmidt, Tuberculosis Institute of Chicago and Cook County, 343 South Dearborn Street, Chicago 4, Ill.

GOVERNMENT OF THE DISTRICT OF COLUMBIA, WASHINGTON, D. C.

Graduate nurses for staff duty in Glenn Dale Tuberculosis Sanatorium located 15 miles from the Nation's Capitol. Salary \$2,644.80 per annum. Apply Director of Nursing, Glenn Dale Sanatorium, Glenn Dale, Md.

Negro Woman Health Education Worker. Capable of executing an extensive health education program. B.A. degree, 12 years' experience as social worker. 3 years as Health Education

Secretary for County Association. Special training in field of Tuberculosis control. Write Box H-542. Employment Service. A.P.H.A.

Woman Biologist, M.A., D.Sc., several years' experience in morphology, experimental pathology, interested either academic position or industrial research. Write Box L-541. Employment Service. A.P.H.A.

Health Educator, female, experienced in promotion and organization of community activities. Prepared to handle complete details of new program to formulate policies, train personnel, act as liaison between community agencies. B.S. degree in Health Education. Present employment with voluntary health agency. Minimum salary \$4,000. Write Box H-540. Employment Service. A.P.H.A.

Sanitarian with more than six years' experience in various phases of environmental sanitation inclusive food, water, and insect control desires position. Holds Canadian Public Health Association certificate as Sanitary Inspector. Write Box E-522. Employment Service. A.P.H.A.

Sanitary Engineer B.S. 12 years' experience in public health engineering with State and Federal Agencies and Army. Some graduate work; currently on terminal leave; desires position in official agency or private industry; free to travel. Write Box E-520. Employment Service. A.P.H.A.

Milk and Food Specialist. Young man with eight years of experience in milk and food sanitation and its allied fields, last five years with U. S. Public Health Service, Master's degree. Desires position as director of division or comparable industrial position. Write Box M-438. Employment Service. A.P.H.A.

Physician, woman, 34 years old, M.P.H. 1947 (Harvard), graduate of recognized Central European Medical School, U. S. citizen. Approved internship, residencies in surgery, obstetrics, medicine (including geriatrics). Clinical teaching experience in obstetrics. 2 years' private practice. Interested in openings in maternal and child health, school health, or general administrative work with official or voluntary agency. Write Box C-419. Employment Service. A.P.H.A.

Health Educator, woman, Negro, M.A. in Health Education (University of Michigan); 14 years' teaching experience in schools as well as community health education; last two years Executive Secretary of national agency engaged in promotion of volunteer health programs. Writing and editorial experience. Write Box H-544. Employment Service. A.P.H.A.

Bacteriologist, M.P.H., University of Michigan. Woman, 28. Now employed. Background in bacteriology and chemistry of milk and water and in bacteriology and epidemiology of communicable diseases. Some academic work in administration. Research experience in industrial wastes. Four years' practical experience in a State Board of Health Laboratory. Write Box L-545. Employment Service. A.P.H.A.

Parasitologist, B.S. (major in biology), graduate work (27 credits) in parasitology and protozoology. Male, 28 years, married, 6 years' laboratory experience in parasitology and serology. Experience includes work in armed forces, university research laboratory, industrial research laboratory. Write Box L-547. Employment Service. A.P.H.A.

Bacteriologist with a M.S.P.H. and a Ph.D., minor in chemistry; over 9 years' experience in all phases of diagnostic bacteriology and serology in a State Health Laboratory, with specialization in the serology of syphilis and other diseases; some teaching and considerable research experience. Seeking a position in the East with research opportunities, in industry, public health, or educational institution. Write Box L-549. Employment Service. A.P.H.A.

Chemist, Virologist, B.A., experience in research on pathogenic viruses (Army Bacteriological Warfare Project), as well as in micro-spectrophotometric vitamin analyses in nutrition survey. Male, single, will travel. Write Box L-543. Employment Service. A.P.H.A.

Nutritionist, Home Economist, female, 28 years, M.A., 8 years' hospital and community experience; teaching experience. Member A.D.A. and A.H.E.A. New York preferred but will travel. Write Box N-417. Employment Service. A.P.H.A.

*Advertisement***Opportunities Available**

WANTED—(a) Public health nurse executive to direct infant welfare agency; extensive experience prenatal, infant welfare and pediatrics required; must have ability to direct large staff of public health nurses; \$6,000. (b) Outpatient supervisor; teaching clinic averaging 100,000 visits annually affiliated with medical school and hospital; \$3,000–\$5,000; East. NEWS FROM THE FIELD

DR. MUSTARD BECOMES NEW YORK CITY COMMISSIONER OF HEALTH

Harry Stoll Mustard, M.D., on November 3 was appointed Commissioner of Health of the City of New York by the Mayor, the Honorable William O'Dwyer. He succeeds Israel Weinstein, M.D., Commissioner since May 24, 1946, who resigned for personal reasons.

Since 1940, Dr. Mustard has been Director of the Columbia University School of Public Health, New York, from which he is taking an indefinite leave of absence to fill the new position. He is retiring President of the American Public Health Association, having also edited the JOURNAL between 1941 and 1944.

Dr. Mustard's experience in public health, going back to 1920, is a varied one. After teaching in his alma mater, the Medical College of South Carolina, he served successively as scientific assistant in the U. S. Public Health Service, Preston County (W. Va.) Health Officer, Director of the Commonwealth Fund's Child Health Demonstration in Rutherford County (Tenn.), Associate Professor of Public Health in The Johns Hopkins School of Hygiene and Public Health, Hermann M. Biggs Professor of Preventive Medicine at New York University College of Medicine and, since 1940, as Professor of Public Health Practice and Director of Columbia University School of Public Health.

During the summer of 1947, Dr. Mustard was a representative of the Association at the meeting of the Royal Sanitary Institute in Torquay, England. During the recent 75th Annual Meeting of the Association in Atlantic City, he was one of three members of the Association to be presented with Honor-

ary Fellowship in the British Society of Medical Officers of Health.

Dr. Mustard is the author of *Cross Sections of Rural Health Progress*, 1930; *An Introduction to Public Health*, 1935, 2nd ed., 1944; *Rural Health Practice*, 1936; and *Government in Public Health*, 1945.

NATIONAL TUBERCULOSIS ASSOCIATION TO HAVE NEW MANAGING DIRECTOR

The resignation of Kendall Emerson, M.D., as Managing Director of the National Tuberculosis Association after nearly twenty years with the organization was announced on September 30, the resignation to become effective January 1, 1948.

Dr. Emerson was appointed to his present post in 1928, coming from the practice of orthopedic surgery in Worcester, Mass., and after an extended military and Red Cross experience in World War I. Twenty Years ago the N.T.A. had about 1,750 affiliated associations. Under Dr. Emerson's leadership the tuberculosis control movement has grown until there are now 3,000 associations in affiliation with the N.T.A., located in every state, the District of Columbia, Puerto Rico, Hawaii, Alaska, and the Canal Zone. The services of the Association during the same period were broadened to include rehabilitation, industrial and adult health education programs. At the same time increasing emphasis was placed on medical research with the result that a separate division on medical research was created in 1947 and grants have been made to 18 investigators for the current fiscal year. Dr. Emerson has been a consultant to the U. S. Public Health Service, a counselor of the Medical Council of the Veterans' Admin-

istration, and a trustee of Smith College. From 1931 to 1935 he served as Executive Secretary of the American Public Health Association. At the 1947 meeting of the N.T.A. he was awarded the Trudeau Medal annually presented by the Association for notable accomplishments in the tuberculosis field. After his retirement Dr. Emerson expects to make his home in Norwalk, Conn.

The appointment of James E. Perkins, M.D., Dr.P.H., Deputy Commissioner of the New York State Department of Health, Albany, to succeed Dr. Emerson as Managing Director of the N.T.A. was announced on October 3. A native of Minnesota, Dr. Perkins was graduated in medicine from the State University in 1930, receiving the Doctor of Public Health degree in 1933 from Johns Hopkins School of Hygiene and Public Health where he made tuberculosis his special focus of interest. Dr. Perkins has served the New York State Department of Health as epidemiologist, as district health officer, and director of the Division of Communicable Disease, and finally as Deputy Commissioner. In 1945 he served for several months in Italy with the Medical Nutrition Mission. Dr. Perkins has served for several years as Secretary of the Epidemiology Section, A.P.H.A., and for six years was Associate Editor of the *American Journal of Public Health*.

NEW EDITOR OF SURVEY MIDMONTHLY

Thomas Devine became Executive Editor of *Survey Midmonthly*, national magazine of social work, effective with the October number. He succeeds Bradley Buell who resigned to become Director of Community Surveys, Inc. During the past dozen years, Mr. Devine has directed many local community surveys and was chief of the Civilian War Services Branch of the Office of Civilian Defense in Washington. He is the son of Edward T. Devine, first

Editor of *The Survey*, and distinguished leader of social work's pioneer days.

MRS. WICKENDEN FIRST NURSE TO RECEIVE MEDAL FOR MERIT

In a ceremony in Washington, D. C., on September 17, Mrs. Elmira Bears Wickenden of Bronxville, N. Y., was awarded the Medal for Merit by Thomas Parran, M.D., Surgeon General of the U. S. Public Health Service, for the President of the United States.

During the war, Mrs. Wickenden served as Executive Secretary of the National Nursing Council for War Service. The Medal for Merit was given in honor of her outstanding contribution to her country during World War II. The citation said, in part:

Elmira Bears Wickenden, for exceptionally meritorious conduct in the performance of outstanding services to the United States from October, 1941, to December, 1946. Mrs. Wickenden, through her 25 years of experience and background in the field of nursing, pointed out to the Nation the need for a unified nursing profession in the effective prosecution of the war. Her superior organizing talent and energetic action led to the establishment of the Nursing Council on National Defense, which later became the National Nursing Council for War Service.

Mrs. Wickenden is the first nurse and third woman in the history of the United States to be awarded the Medal for Merit by the President of the United States.

COLORADO STATE LABORATORY EXPANDS SERVICES

The Central Laboratory of the Colorado Department of Public Health, in order to fill numerous requests of physicians will add total protein in spinal fluids, new rapid culture for tubercle bacilli, typing of organisms of the enteric group, mycology and laboratory evaluation to its services. All licensed physicians in the state may avail themselves of these services.

APPOINTMENTS IN VIRGIN ISLANDS DEPARTMENT OF HEALTH

Dr. Kund Knud-Hansen has retired as Commissioner of Health after many years of government service. The Acting Commissioner is Dr. John S. Moorhead, a native of St. Croix. After seven years of service, Dr. Norman D. Thetford, St. Croix, has taken a terminal leave from the post of Assistant Commissioner of Health and Chief Municipal Physician. Dr. Roy A. Anduze, a native of St. Thomas, will succeed him on a temporary basis.

The Virgin Islands Department of Health operates general hospitals and clinics and performs the usual functions of a state health department. The two top positions, commissioner of health and chief municipal physician for St. Thomas and assistant commissioner of health and chief municipal physician for St. Croix, are both federal posts in the U. S. Department of Interior.

INTERNATIONAL UNION AGAINST THE VENEREAL DISEASES

The first post-war General Assembly of the International Union against the Venereal Diseases was held in Paris, October 20 to 25. The program of the Assembly was developed under four main heads:

1. Collaboration with the medical profession
2. Treatment of syphilis by penicillin
3. The social campaign against venereal diseases
4. Sexual conduct and the venereal diseases

The post-war program objective of the Union is the establishment of world-wide service through a series of regional offices. The first to be set up is the Regional Office for the Americas, operated for the Union by the American Social Hygiene Association at its headquarters at 1790 Broadway, New York.

William F. Snow, M.D., is the President of the International Union. Other

members of the United States delegation at the recent General Assembly were:

James A. Doull, M.D., Chief of the U. S. Public Health Service, Office of International Health Relations
J. R. Heller, Jr., M.D., Chief, U. S. Public Health Service, Venereal Diseases Division
Miss Jean B. Pinney, Director of the Union's Regional Office for the Americas at 1790 Broadway, New York

The Secretary-General of the Union is Dr. Andre Cavailon of France.

AMERICAN RED CROSS NATIONAL BLOOD PROGRAM

After several months of intensive study and consideration with medical and health leaders, the American Red Cross has adopted a National Blood Program. Its purpose is to provide for medical use, without charge for the products, sufficient blood and blood derivatives throughout the nation to help save lives and prevent needless suffering.

The phases of the program for supplying blood and blood products for medical use are:

1. Collecting blood
2. Processing it for use as whole blood and blood derivatives, including packing and storage
3. Distribution of both the blood and the blood products for use by physicians and hospitals for any patient needing them
4. Continuous research and investigation of the quality of the products, their safety, and important uses

The announcement of the program indicates that it will be one of gradual development with not more than 20 or 25 carefully selected centers set up in the first year. It is estimated that it may take from three to five years for the program to reach full operation.

NEW MEMBERS OF THE FEDERAL HOSPITAL COUNCIL

Announcement has been made of the appointment of the following new members to the Federal Hospital Council

established last year to assist Surgeon General Thomas Parran of the U. S. Public Health Service in the administration of the hospital survey and construction program:

Nelson Cruikshank, Director of Social Insurance Activities of the American Federation of Labor

James A. Paullin, M.D., Professor of Clinical Medicine, Emory University and former President of the American Medical Association and the American College of Physicians

Joseph W. Fichter, Master of the Ohio State Grange

SEATTLE AND KING COUNTY JOIN HANDS

Early in September, the Seattle, Wash., Health Department assumed responsibility for the administration of the activities formerly carried by the King County Health Department. The merger was effected by a city council committee in cooperation with the county commissioners and is designed to provide better health protection both within the county and city at less cost.

Emil E. Palmquist, M.D., Health Director of the City of Seattle will serve as chief administrative officer of the merged department but final consolidation must await state legislative action.

COURSES IN THE LABORATORY DIAGNOSIS OF PARASITIC DISEASES

Three 6 week refresher courses for laboratory personnel in the Laboratory Diagnosis of Parasitic Diseases will be offered during 1948 by the Laboratory Division of the Communicable Disease Center of the U. S. Public Health Service in Atlanta. The dates are: January 12-February 20; July 12-August 20; and October 11-November 19.

This training is open to all grades of employed laboratory personnel and is given primarily for workers in laboratories of state and local public health departments. Applicants from hospitals and private laboratories will also be considered when vacancies occur.

There is no tuition or laboratory fee

but travel and living expenses must be paid for by the individual or his employer. Such expenses can be paid from Title VI funds.

Applications should be made as early as possible. Notification of acceptance will be made approximately two months before the course begins so that states may have time to arrange budgetary allotments.

Laboratory directors and senior staff members may attend these 6 week courses. However, one or two short courses in the Laboratory Diagnosis of Parasitic Diseases will be scheduled for such workers. Definite dates have not been set, but those interested should indicate their first and second choice of the following 1948 dates: March 8-19; May 10-21; and December 6-17.

Address further inquiries to the Laboratory Division, Communicable Disease Center, U. S. Public Health Service, 291 Peachtree Street, Atlanta, Ga.

HONORARY FELLOWSHIPS PRESENTED IN BRITISH SOCIETY OF MEDICAL OFFICERS OF HEALTH

Three members of the American Public Health Association were presented honorary fellowships in the British Society of Medical Officers of Health at the 75th Annual Meeting of the A.P.H.A. in Atlantic City, October 7.

Presentations for the British society were made by Sir Allan Daley, Medical Officer of Health of the London County Council, to:

Thomas Parran, M.D., Surgeon General of the U. S. Public Health Service

Harry S. Mustard, M.D., President of the Association and Director of the Columbia University School of Public Health

George K. Strode, M.D., of New York City, Director of the Rockefeller Foundation's International Health Division

Sir Allan declared the Society was citing the three as "eminently distinguished in public health."

Membership of the 90 year old British Society, numbering approximately 2,000, is made up of administrative health officers of local health departments in Britain.

MARKLE FOUNDATION'S POST-FELLOWSHIP GRANTS

The John and Mary R. Markle Foundation announces a new program in coöperation with medical schools of the United States and Canada for the purpose of relieving the teacher-investigator shortage in the schools. In the academic years, 1948-1949, it will inaugurate "Post-Fellowships" to aid young scholars in medical science. The program will provide an opportunity for promising scientists to develop as teachers and investigators capable of making important contributions to medical science.

The plan resulted from the Foundation's survey which showed many potential teachers and investigators drawn away from academic medicine when lack of trained investigators limited the use of sums available for fundamental research. The scientists will be known as "Scholars in Medical Science." They will be recommended by the medical schools, and final choice will be made by regional committees of the Foundation. Neither the number of scholars nor the exact amount of the scholarships is fixed but will depend upon existing circumstances.

Persons interested in being considered as candidates for these Post-Fellowships must do so through their own medical schools.

FILM ON PECKHAM EXPERIMENT

Expected for release in November, 1947, is a documentary film record of the Peckham Experiment and its Pioneer Health Centre in England. The film has been described as "an epic documentary presentation of social activities." It will be distributed abroad as

well as in England. Requests for booking the film should be directed to the British Embassy in Washington, D. C.

ANNUAL DANA MEDAL TO DR. VERHOEFF

At the Faculty Luncheon of the American Academy of Ophthalmology and Otolaryngology in Chicago recently, Frederick H. Verhoeff, M.D., Professor Emeritus of Ophthalmic Research at Harvard Medical School and Consulting Chief of Ophthalmology at the Massachusetts Eye and Ear Infirmary, received the Leslie Dana Gold Medal awarded annually for outstanding achievement in the prevention of blindness and the conservation of vision.

GEORGE J. NELBACH RETIRES

On September 1, 1947, George J. Nelbach retired as Executive Secretary of the State Committee on Tuberculosis and Public Health in the New York State Charities Aid Association after 40 years of service. During this period, a network of 62 county and city tuberculosis and health associations was organized in the state. Not only has the state committee been active in the eradication of tuberculosis during these 40 years but it has also taken part in the development of New York State's health legislation as well as in campaigns to reduce diphtheria, control venereal diseases, and organizing adequate community health programs.

Robert W. Osborn, a Staff Assistant since 1924, has been appointed Acting Executive Secretary to succeed Mr. Nelbach.

CHLORINE, CHLORAMINE, AND CHLORINE DIOXIDE

The procedure for determining quantitatively the amount of free chlorine, chloramine, chlorine dioxide, and sodium chlorite in water containing a mixture of these constituents was the subject of a paper presented by Dr. John F. Haller

and S. S. Listek before the Water, Sewage and Sanitation Section of the American Chemical Society during their recent Annual Meeting.

The method described consists of four amperometric titrations with sodium arsenite. Free chlorine is determined by titration of a sample from which chlorine dioxide has been removed by hydrolysis at alkaline pH. A second titration, in the presence of iodide, gives the combined concentration of chlorine and chloramine. A third titration, in neutral solution, gives the combined concentration of chlorine, chloramine and one-fifth of the chlorine dioxide. After acid hydrolysis, a fourth titration in neutral solution gives the total oxidizing capacity, thus permitting the calculation of chlorine content.

AMERICAN HOSPITAL ASSOCIATION

At the recent meeting of the American Hospital Association in St. Louis, the following officers were elected:

President: Edgar C. Hayhow, Director, East Orange (N. J.) General Hospital

President-Elect: Jessie Turnbull, Administrator, Elizabeth Steel Magee Hospital, Pittsburgh, Pa.

First Vice-President: George U. Wood, Superintendent, Peralta Hospital, Oakland, Calif.

Second Vice-President: Ray Amberg, Superintendent, University Hospitals, Minneapolis, Minn.

NORTH CAROLINA HOSPITAL PLAN APPROVED

The Raleigh (N.C.) *News and Observer* of July 12 carried a detailed account of the state-wide meeting of the North Carolina Good Health Association in Greensboro the previous day. At this meeting, Surgeon General Thomas Parran announced formal approval of the plan for hospital construction submitted by the North Carolina Medical Care Commission, of which John A. Ferrell, M.D., is Executive Secretary.

Dr. Parran further announced his approval of the state's application to

receive \$3,431,550 for construction of hospitals during the current year.

At the same meeting, Josephus Daniels presented band leader Kay Kyser with a silver tray "on behalf of all the people of North Carolina for his magnificent contribution to the good health program."

By September 15, five state hospital construction plans had been approved by the Surgeon General—those of Mississippi, Indiana, North Carolina, Oklahoma, and Illinois.

MCGILL TO GRANT DEGREE IN TROPICAL MEDICINE

The wartime short course in tropical medicine at McGill University Faculty of Medicine, Montreal, has been revised and additional facilities have been provided for study leading to a D.T.M. degree. The course is being conducted by the Department of Health and Social Medicine with the assistance of members of other faculties of the university. The final third of the course is a period of specially arranged supervised training in tropical countries. This includes clinical hospital practice and health unit work. For further information address the Chairman, Department of Health and Social Medicine, 490 Pine Avenue, West Montreal, Canada.

DR. ALTLAND APPOINTED ACTING COMMISSIONER, MICHIGAN DEPARTMENT OF HEALTH

John K. Altland, M.D., M.S.P.H., formerly Director of the Bureau of Local Health Services, Michigan Department of Health, has been appointed by Governor Sigler as Acting Commissioner, succeeding William DeKleine, M.D., who had been State Commissioner of Health since 1944.

Dr. Altland, who is a native of Michigan, received his medical degree from the University of Michigan School of Medicine in 1928, and his master's degree from the Michigan School of Public

Health in 1938. He served for several years as Director of county departments of health and for a period of a year and a half with the U. S. Public Health Service, returning to the State Department of Health as Director of Local Health Services in April, 1946.

LECTURES TO THE LAITY

The thirteenth series of the New York Academy of Medicine Lectures to the Laity is now in progress. The general title of the 1947-1948 series is "Perspectives in Medicine." Five of the series of seven remain to be given. They are as follows:

December 17, "Food and Civilization," Sir Raphael Cilento

January 22, "On Being Old Too Young," Edward J. Stieglitz, M.D.

February 4, "Perspectives in Cancer Research," Cornelius P. Rhoads, M.D.

February 26, "Psychiatry for Everyday Needs," William C. Menninger, M.D.

March 11, "The Inter-relation of Pure and Applied Science in the Field of Medicine," James B. Conant, Ph.D.

All lectures begin at 8:30 P.M. The general public is admitted without charge and the audience is invited to submit questions at the end of each address.

ANTIMALARIAL DRUG SURVEY

PUBLISHED

The Office of Technical Services of the U. S. Department of Commerce announces recent publication of a three volume summary of efforts made in this country's wartime quest of superior antimalarial drugs. Coördinated by the Committee on Medical Research, Office of Scientific Research and Development, the investigations described were carried out between 1941 and 1945 by hundreds of universities, pharmaceutical companies, and various governmental and private laboratories under OSRD contracts. Intended to "expedite research for still better antimalarial drugs and to

establish a pattern for systematic chemotherapeutic studies of other infections," the survey was edited by Frederick Y. Wiselogle, Professor of Chemistry at The Johns Hopkins. The set of three-bound volumes sells for \$30 and is obtainable from the publisher, J. W. Edwards, Ann Arbor, Mich. The Office of Technical Services has photostat and microfilm copies for sale.

FOURTH INTERNATIONAL CONGRESSES ON TROPICAL MEDICINE AND MALARIA

A preliminary announcement of the Fourth International Congresses on Tropical Medicine and Malaria states that the conference will be held in Washington, D. C., during the period May 10-18, 1948. Actually, it will be a joint meeting of the Fourth International Congress on Tropical Medicine and the Fourth International Congress on Malaria. Invitations to participate have been extended to more than sixty governments. The official languages of the Congresses are English, French, and Spanish. Scientific papers should be prepared in one of those languages.

For further information communicate with Dr. William A. Sawyer, Executive Secretary, Fourth International Congresses on Tropical Medicine and Malaria, Department of State, Washington 25, D. C.

PERSONALS

Central States

ROBERT H. BISHOP, JR., M.D.† has resigned as director of University Hospitals, Cleveland, Ohio, to become director of the newly formed Joint Committee for the Advancement of Medical Education and Research. This committee has been formed to make Cleveland the outstanding medical center in the Middle West. Dr. Bishop served the city of Cleveland

* Fellow A.P.H.A.

† Member A.P.H.A.

as its first director of the department of tuberculosis and later as health commissioner.

GRAHAM L. DAVIS,[†] Director of the Hospital Division of the W. K. Kellogg Foundation, Battle Creek, Mich., was elected President of the American Hospital Association, Chicago, Ill., at its 49th Annual Convention held in St. Louis, Mo., September 22-25.

CHANGES IN INDIANA STATE BOARD OF HEALTH

GEORGE W. BOWMAN, M.D., who has been in charge of Venereal Disease Control Activities for several years, is being loaned to the Indianapolis City Board of Health to help them in venereal disease control and to continue to work at the rapid treatment center in which work he has played an important part in recent years. Dr. Bowman's work at the State Board of Health will be continued by CARL C. KUEHN, M.D.

GEORGE ERGANIAN, is now working on sewage and refuse disposal in the Division of Sanitary Engineering.

ANN ELIZABETH POORMAN, R.N., began her duties as a hospital consultant nurse for the Division of Hospital and Institutional Services in July.

RUBY ROGERS, has been appointed Medical Social Service Consultant. She was formerly consultant in the Division of Services to Crippled Children, State Department of Public Welfare.

FRANK D. WRIGHT, has been assigned to the Northeastern Branch Office at Ft. Wayne as Assistant Sanitary Engineer.

Eastern States

MORTON L. LEVIN, M.D., has been appointed Assistant Commissioner for

Medical Administration with the New York State Department. He was formerly Director of Cancer Control. He is President of the Public Health Cancer Association of America and of the Society for the Study of Mass Medicine.

REMA C. FITCH,[†] formerly with the Aluminum Company of America, New York, N. Y., has been appointed Senior Sanitary Engineer of the Arizona State Department of Health.

YOLANDE LYON,[†] was recently appointed Executive Director of the American Diabetes Association, which recently transferred its executive offices from Cincinnati, Ohio, where it has been located since 1940, to Brooklyn, N. Y. The appointment of an executive director is the first step in the association's war-postponed plans for expansion of its program. Miss Lyon was formerly with the Medical Society of the State of New York as field representative, assistant to the public relations director and consultant on program to the Women's Auxiliary of the Society.

LOUISA WILSON, has been appointed public relations director of the Welfare Council of New York City.

Southern States

CHANGES IN FLORIDA HEALTH OFFICERS:

M. LEWIS GRAY, M.D., formerly of Wilmington, N. C., has been appointed health officer of the Jackson-Washington County health unit with headquarters at Marianna. Dr. Gray succeeds C. A. ADAMS, JR., M.D., who resigned to enter private practice.

HARRY W. HOLLINGSWORTH, M.D., has been appointed Health Officer of the Highlands-Glades-Hendry county health unit, with headquarters at Sebring. Dr. Hollingsworth succeeds JAMES HALL, M.D., who resigned to accept a position on the state level.

^{*} Fellow A.P.H.A.

[†] Member A.P.H.A.

ELLSWORTH H. JOHN, M.D.,† former Health Officer of the Meade, Breckenridge, Hancock tri-county health department of Kentucky, has been appointed Health Officer the Suwannee - Dixie - Lafayette County health unit with headquarters at Live Oak. He succeeds WILLIAM G. C. HILL, M.D., who transferred to the Putnam-Flagler county health unit.

PAUL H. JENKINS, M.D., recently released from the Army assumed his duties as county health officer of Marion County on October 1.

H. A. SAUBERLI, M.D.,† formerly with the Tennessee State Health Department has been appointed Health Officer of the Leon County Health Department with headquarters at Tallahassee. Dr. Sauberli succeeds BRUCE UNDERWOOD, M.D.,† who resigned to enter private practice.

JAMES A. GRIDER, JR., M.D.† who for some years has been assigned to the El Paso office of the Pan-American Sanitary Bureau, has been transferred to the U. S. Public Health Service Hospital at Fort Worth, Tex. He is succeeded in El Paso by M. F. HARALSON, M.D., of the Public Health Service who will also succeed him as Secretary of the United States-Mexico Border Public Health Association.

LOWELL S. SELLING, M.D.* has been appointed consultant on Mental Health, Florida State Board of Health. He is the author of *Men Against Madness*.

JAMES A. SPROLES, JR., M.D., became Director of the Adams County, Miss., Health Department July 1, succeeding KENNETH W. NAVIN, M.D., who became District Supervisor for

the Mississippi State Board of Health. Prior to entering the Army in 1944, Dr. Sproles was Health Officer for Marion County. He has also been health director for Alcorn and Tishomingo counties..

LINFIELD S. WILDER, M.D., will head the new Montana State Mental Hygiene Division, set up by the 1947 legislature as a part of the Division of Hospital Administration. Dr. Wilder's previous experience has been with the U. S. Public Health Service and the St. Louis Psychopathic Hospital.

Western States

JESSIE M. BIERMAN, M.D.,* Chief of the Bureau of Maternal and Child Health, California State Department of Health, has resigned to become Professor of Maternal and Child Health at the University of California School of Public Health.

ALMON D. BLANCHAT, M.D., has assumed the post of Linn County, Ore., Health Officer. He has most recently served on active duty with the U. S. Navy with the ultimate rank of lieutenant.

MONROE EATON, M.D., Director of the Virus Laboratory, California State Department of Health, resigned recently to join the faculty of Harvard University Medical School, Boston, Mass., as Associate Professor of Bacteriology.

J. C. GEIGER, M.D.,* Director of Public Health, San Francisco, Calif., was awarded the Presidential Medal of Merit by His Excellency Victor M. Roman, President of the Republic of Nicaragua, with the following citation: "For medical services to humanity throughout the world and in particular to the Nicaraguan colony residing in San Francisco."

RAYMOND F. GOUDEY,* formerly of the Department of Water and Power,

* Fellow A.P.H.A.
† Member A.P.H.A.

City of Los Angeles, Calif., recently accepted the position as Director of the new Sanitary Engineering Division of Truesdail Laboratories, Inc., of Los Angeles.

PORTIA IRICK, R.N.,* who for some years has been Director of Nursing Service for the Pacific Area, American Red Cross, San Francisco, Calif., has resigned to become Director of the Nursing Division in the New Mexico State Department of Health, Santa Fe.

LEONARD M. KAHL, has been appointed Health Officer for Clatsop County, Oregon.

ALFRED E. KESSLER, M.S.P.H.,* who has served for several years as Executive Secretary of the Denver Tuberculosis Society, Denver, Colo., has resigned to accept appointment as the Executive Secretary of the Marion County Tuberculosis Association, Indianapolis, Ind.

EVANS G. NELSON, D.D.S., is Director of the Dental Hygiene Section of the Oregon State Board of Health. Graduating from the University of Oregon Dental School in 1945, he was until recently on active duty with the U. S. Navy both in continental U. S. and overseas.

CHARLES M. MCGILL, M.D.,† Director, Industrial Hygiene, Oregon State Board of Health, has resigned to enter private practice of industrial medicine in Tacoma, Wash. He will also act as Medical Director for the Tacoma Smelter. Pending the employment of a full-time director to replace Dr. McGill, CARLYLE THOMPSON, M.D., Director, Preventive Medicine Division, will assume administrative charge of the section. RALPH R. SULLIVAN, M.D.,† Director, Venereal Disease Control, will act as consultant in industrial derma-

tology and KENNETH N. FLOCKE, Industrial Hygiene Engineer, will be in charge of technical activities.

ARTHUR E. RIKLI, M.D.,† Director of the Montana Division of Tuberculosis Control, is taking graduate instruction at Johns Hopkins University in Baltimore.

J. P. WARD, M.D., M.P.H.,* has been appointed Superintendent of Public Health, State of Arizona, succeeding GEORGE F. MANNING, M.D.,† resigned. Dr. Ward has most recently been Commissioner of Health of Colquitt County, Georgia, and has also been a local health officer in Mississippi. He also served with the Medical Division of UNRRA following the late war.

DEATHS

WARREN PEARL MORRILL, M.D., Director of Research for the American Hospital Association and long active in hospital work in the United States and Canada, died September 28 at Passavant Memorial Hospital, Chicago, after an illness of two months. He was 70 years old.

HENRY N. OGDEN, of the New York State Public Health Council died September 29. Professor Ogden served on the Public Health Council from the year of its formation, 1913. As a practising engineer, he designed and built sewerage systems in Ithaca and Binghamton, N. Y., Sand Point, Ida., Popham Beach, Me., and Richmond, Va.

AMERICAN PUBLIC HEALTH ASSOCIATION

1790 Broadway at 58th Street

New York 19, N. Y.

American Journal of Public Health

and THE NATION'S HEALTH

Index to Volume 37, 1947

How to Use the INDEX

This is an Index to all the reading matter in the JOURNAL. It is essentially a title and author Index, although occasional subject headings are provided.

Articles, committee reports, and editorials are listed alphabetically according to the key words in the title, with many cross-references.

Editorials are indexed under "Editorials" as well as alphabetically under the key words in the title.

News notes and fillers are indexed under "News from the Field." This section should be searched as supplemental to the title index.

Matters pertaining to the Association are indexed under "American Public Health Association."

Book reviews are indexed under "Books and Reports."

Obituaries are indexed under "Death Notices."
